The Meat Industry in the United Kingdom.

The Breeding of Beef Cattle. — This brings us to the question of the conduct of the meat industry in the United Kingdom. As has been indicated, the methods of handling cattle for food in the United Kingdom do not at present partake of that kind of specialisation which exists in other countries. We have undoubtedly specialised the breeding of cattle more than any other nation, and our leading beef breeds—the Aberdeen-Angus, the Herefords, the Devons, the Galloways—are known in many parts of the world, as are also our dual-purpose breeds, the Shorthorns, Lincoln Reds, and Red Polls. The meat purveyor, however, has only an academic interest in the breeding of cattle and the specialisation of breeds; what he wants is an animal that will, when dressed, give him a minimum of bone to flesh, and a high percentage of carcass to live weight. Curiously enough, however, this aspect of the matter has only been recognised by breeders since 1895, previous to which date there was no recognition of the meat purveyor at our fat stock shows. As a consequence, what are known as "breeders' points" came into vogue, and, translated into actual practice, meant excessive fat of comparatively low value. It was in 1895 that the Smithfield Club of London, which holds the most notable fat stock show in the United Kingdom every year, provided a class for what is now known as the "block test," which means that

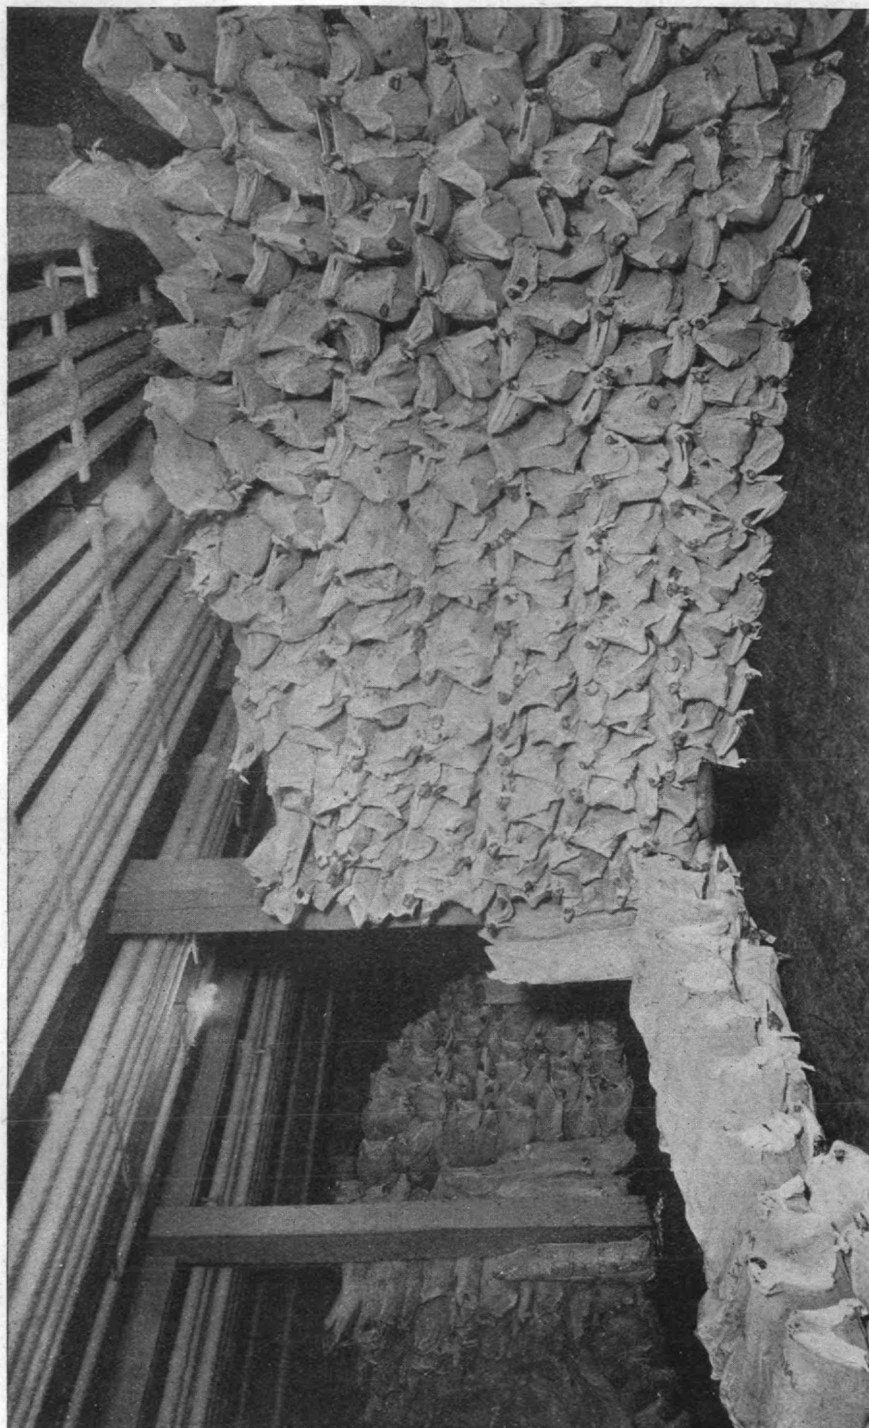

FIG. 3.—FROZEN MEAT IN COLD STORE BELONGING TO THE GOVERNMENT'S PRODUCE DEPARTMENT, ADELAIDE, SOUTH AUSTRALIA.

Hosted by Google

animals have first of all to be judged alive, and subsequently judged in the carcass. Since 1895 this feature has been introduced at many fat stock shows, with the consequence that it has been of such high educational value that the breeders' standards are gradually being compelled to conform to the standards required by the carcass. This is very well illustrated by the fact that, so far, it has been found impossible to make the awards given to cattle at the Smithfield Show agree with the awards of the carcass meat, which is a demonstration of the absence of proper values corresponding in figures to various points of excellence. The figures for

the meat purveyor. This transition in meat production is, however, far from being complete, and there is something wanted still in the judging of animals, so as to make the points of the live animal correspond to the points of the 1911 Smithfield Show exhibit a very good illustration of this.

One of the notable features in these carcass competitions would seem to be the determination of the dressing-out weight, which, in the best

class of animals, seems to reckon out at between 60 and 65 per cent.

The products from cattle at these carcass competitions are such as are generally recognised throughout the United Kingdom, and consist of:—

1. The carcass.
2. Suet, caul, reed fat.
3. Fat, gut fat, trimmings.
4. Tongue, tail.
5. Head, feet.
6. Heart, liver, lights.
7. Tripe, feck, reed.
8. Hide.
9. Intestines.

and form the basis upon which the meat industry is conducted.

The Slaughtering of a Bullock.—It will be opportune to mention here briefly the methods of slaughter which are adopted in the United Kingdom. The bullock is stunned with either a pole-axe, pistol, or humane slaughtering apparatus, a perforation being made in the middle of the roof of the cranium, which causes immediate unconsciousness due to concussion. The Jewish method, in which stunning is not adopted, is conducted by severing the arteries and blood-vessels of the neck, and it is also permitted in this country. The first process in the ordinary method of slaughtering* is that of bleeding, which, in the case where animals are previously stunned, is thoracic. The gullet is first of all opened, and the main vessels of the neck (carotid and jugular) are severed.

When the blood has flowed out, the animal is turned on its back, and is supported in this position either with blocks of wood or pritches. The feet are then cut off and the head severed; an incision is made in the hide, right down the forearms to the crown of the chest, and this is continued along the middle line from the chest to the base of the tail. Diagonal lines are then made down the hind legs, and flaying is started. The hide is first of all removed from the breast on the left side, and then on the right, and in order to facilitate operations later on, the breast is then sawn through and the "gips," "izening" bone, or pelvis, is also severed.

Fig. 5.—The Abattoir of the Co-operative Society at Stockton.

A gambrel is inserted under the sinews of the hind houghs, and the carcass is raised by means of a crane or self-sustaining hoist, and is suspended in the half raised position, so as to allow of the hindquarters being "buffed" or flayed. The hide is pulled down, and the tail is liberated. At this point the whole carcass is raised up, so that only the shoulders rest on the floor, and an incision is made near the centre middle line, and the thick fat or "crook" lining the abdomen is at once taken out. The paunch or stomach is then withdrawn, and the intestines, including the liver, are removed. The bed fat, however, lining the

* "The Meat Industry and Meat Inspection," by Gerald Leighton, M.D., and Loudon M. Douglas, F.R.S.E., Vol. II. p. 687.

Hosted by Google

pelvis, and also the kidney fat, should be left undisturbed.

The intestines, being attached to the liver, can be cut free, and as the paunch is attached to the back, at the left side, it can be removed by merely pressing it downwards. The paunch, together with other intestinal offal, is thrown aside, so that it may be dealt with by others than those who handle the carcass.

The gall-bladder is then taken out, and the diaphragm, lungs, and heart are removed, after which the carcass is raised to the vertical position, and, in accordance with local custom, split down the backbone or vertebral column. In Scotland it is customary to split the carcass of a bullock from the front by means of a cleaver. In other parts of the country this same process is carried out from the back, and in some cases the splitting is performed with a heavy cleaver or a saw. In the city of Edinburgh—which may be taken as a typical example of what occurs in Scotland—the carcass is kept entire, after being split down the backbone—that is to say, the two sides are not severed entirely, but are kept united by means of a portion of skin.

FIG. 6.

VIEW OF A CATTLE-SLAUGHTERING BOOTH AT GLASGOW, AND SHOWS THE OLD-FASHIONED WAY OF KILLING ANIMALS.

When the carcass has been elevated to the vertical position, the hide, which at that moment should cover the shoulders only, is finally removed from the forequarters. The kidney fat should then be turned over, and the kidneys removed, the turning over of the fat being meant to give a good dressed appearance. When these operations have been completed, the whole carcass is washed out with warm water, and is wiped free from any blood or other matter which may be adhering to it.

The carcass is then in a finished state, and is at once placed in a position where it will cool, or where the animal heat may be allowed to dissipate. This may either be the hanging hall of an abattoir, or in the open space of a private slaughtering booth, but in any case this pre-cooling should only be allowed to continue until the excess of animal heat has disappeared.

The carcass may then be placed in a chill-room, where available, and chilled to a temperature of 40° F., when, after about twelve hours, it will be in a firm condition, and be capable of being handled for all purposes in connection with the meat trade.

The Carcass.—The handling of the carcass in the United Kingdom is carried on in both public and private abattoirs, and much discussion has taken place during recent years as to the advisability of centralising the whole business of slaughtering and handling of meat products in public abattoirs, the argument being that the ante-mortem and post-mortem examinations can be better carried out in public institutions than in the private establishment. The question of examination, however, with a view to the detection of disease, is only one of the many involved. As our knowledge progresses, we are led to the conclusion that sanitary surroundings are also necessary to the proper conduct of the meat industry, and such conditions do exist in all public abattoirs and many private ones; but I doubt if anyone will argue that the majority of private abattoirs are above suspicion. No doubt a good understanding will yet be arrived at in this matter, and there is no reason why the possessors of private abattoirs should not be recognised as possessing valuable vested interests, which should be met by compensation in the event of the general adoption of public abattoirs

Hosted by Google

throughout the country. Apart, however, from the general question, it must be noted that there is also an economic one which is not generally appreciated—namely, that the profit of handling a bullock in a private abattoir is not nearly so great as in a public institution, and actual figures carefully obtained show the comparison to be much in favour of the public abattoir.

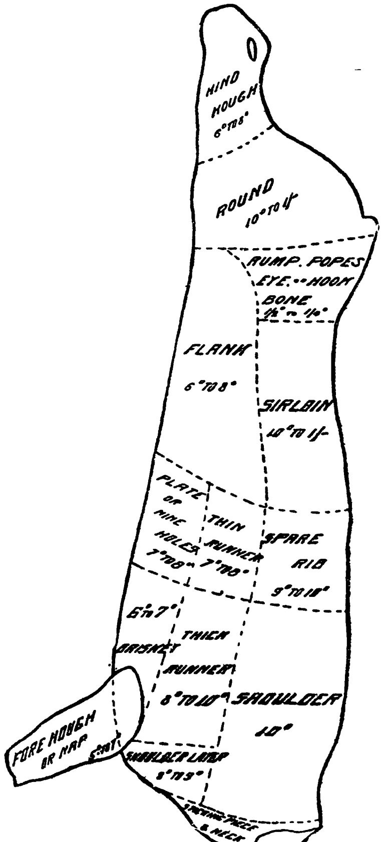

FIG. 7.—DIAGRAM OF A SIDE OF BEEF.
Showing average prices realised throughout the United Kingdom for various cuts.

The Chemistry of the Subject.—Generally speaking, the products of a bullock are two in number, namely, the carcass and the offal, a large portion of the latter being of an edible character. The carcass is built up on a framework of bones supported by tendons, muscles, and ligaments, through and in which the organs of circulation, respiration, digestion, excretion, and reproduction are enclosed, and the whole body is subject to a complex system of brain and nerves, which may be regarded as the motive power of the animal; but although all these various parts exhibit infinite detail, they may be reduced to three principal ingredients, namely, water, ash, and protein or nitrogenous substances, and the specialisation of this fact is what has led to the great development of the meat industry in different overseas countries. The carcass of the bullock is, in fact, looked upon as a source not only of food, but of the raw materials used in many of the arts and sciences. Curiously enough, there is a large quantity of water present in the bullock, which in a half fat animal may be put down at 50 per cent., decreasing to about 43 per cent. in a fat animal. Some parts of the meat, however, such as the round, show as much as 75 per cent. of water. The chemistry of the subject is, indeed, most interesting, and it is curious to note that while the composition of the carcass can be reduced to the three constituents, water, ash, and protein, the same classification may be applied to the plants upon which the animals feed. We have in them also what are known as carbohydrates, which consist of starch, sugar, etc., and which are found in the framework of the plants or stored up in the cells, and the whole science of feeding consists in so balancing the rations as to obtain the quick growth of the flesh at the minimum cost of food. Before this science of feeding was understood, bullocks were not supposed to attain maturity for a good many years. Now, however, the age of the highest grade beef animals at maturity is from twenty-four to thirty months, and the application of scientific methods in this direction has altered entirely our view of what meat ought to be. At the present day we demand that good beef should be of a bright uniform red colour, nicely marbled with fat, and should be firm and elastic, with the appearance of healthy meat juices.

The Cutting Up of the Carcass.—The cutting up of the carcass is carried out differently in various parts of the country, and the names applied differ also. The main principles are the same, and the ruling prices for the different sections work out pretty much to the same value for the whole carcass.

As has been pointed out, the dressing-out weight in the highest class of animals varies between 60 and 65 per cent., and the remainder of the animal consists of blood, fat, hide, and internal organs, and it is from these by-products that many articles of commerce are derived. The number of commodities which may be produced from a bullock is something like 146. A mere list alone, with the briefest possible description, would occupy a considerable length of time in writing. It will only be possible, therefore, to describe the more prominent by-products,

and so by that means illustrate that the subject is a vast one.

Blood.—The first by-product to be obtained from a carcass is the blood, and its uses vary considerably in different countries. In some Continental countries it is utilised for the manufacture of feeding stuffs, which are given to pigs, horses, and poultry. The general practice is to utilise the blood for the manufacture of blood albumen, which is used for a variety of purposes, such as the clarifying of sugar, the fining of liquors, and in dyeing. When the albumen has been separated out—a process which is conducted merely by coagulation—a clotted residue remains, and this is dried into an impalpable powder for the purpose of being used for fertiliser, and as such is worth about £6 per ton.

Fat.—Next in importance to the blood is the

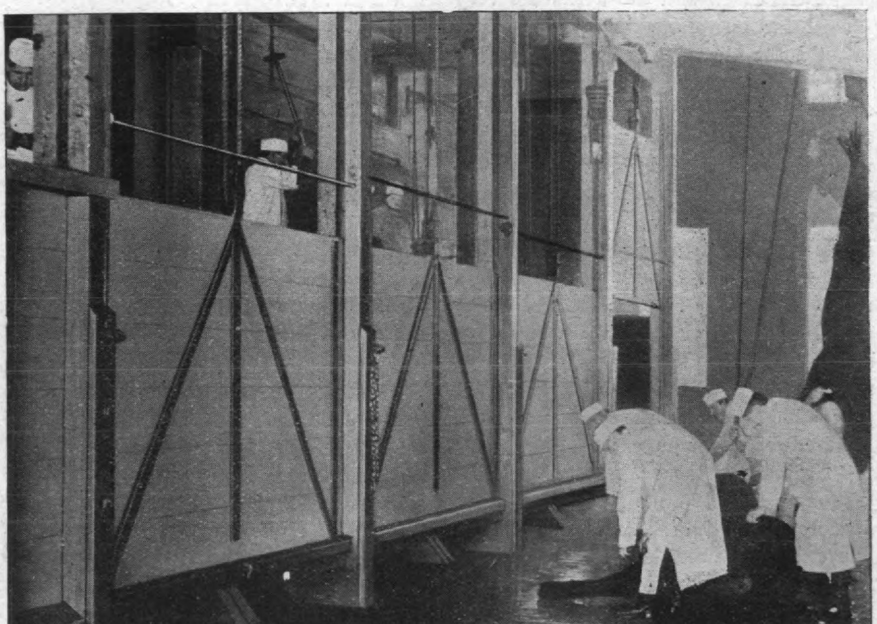

FIG. 8.—INTERIOR OF AMERICAN ABATTOIR.

Showing the knocking-down pens in which all cattle are stunned before being bled. As soon as they fall in the knocking-down pen they are rolled out on to the adjoining floor, and are at once hoisted to a rail on which they are bled.

Hosted by Google

fat, which forms a large portion of the animal weight. Such fat as is not included in the carcass and sold as meat may either find its way to the tallow renderers, or it may be rendered as suet, an article for which there is at present a large demand, and which can only be made from the freshest of material. Another outlet for fat, and perhaps the most important of all, is in the manufacture of margarine, in which case the oleo which forms part of the fat is separated from the stearine, and this latter is used for a variety of purposes, much of it finding its way into lard compounds, which possess the advantage of not being made from lard at all! The residual matter from the fats is carefully preserved and utilised as poultry foods, so that in this department of the business there is no waste whatever. In many of the packing houses in other countries, soap-making, as a continuation of the fat rendering processes, is carried on very extensively, so that the best possible use can be made of this important by-product. Candles also are produced in many factories from the stearine, and enable a very high price to be ultimately realised for this product.

Hoofs, Horns, and Hides.—The hoofs, horns, and hides of cattle form very important raw materials in a department by themselves. The coverings of the hoofs and the horns are very largely used for button-making, the residues being utilised for the manufacture of yellow prussiate of potash, so largely used in the making of the colour Prussian Blue; but the contents of the hoofs and horns find another outlet in the manufacture of gelatine and glue, for which purpose the trimmings of the hides are also utilised, and the finer jellies and gelatines are manufactured largely from such products and used for food purposes. The hides themselves are generally treated by hide merchants, whose business it is to select them and salt them, so preparing them for the tanner, who separates the hair from the hide, the hair being largely used for mixing with lime, and the hides being, of course, utilised for the manufacture of leather.

Bones.—Necessarily, there is a large quantity of bones produced where a number of cattle are handled, more especially if sausages and similar products are manufactured. Bones, in that case, are set free to a very considerable extent, and while they may be utilised on the small scale for grinding in the green state for poultry feeding, they are best utilised by digesting them and so extracting the fat which they contain and also the gelatine. The residue can then be ground up, and forms, as bone meal or ground bones, one of the best permanent fertilisers we use on the farm. Knife-handles, buttons, and ornaments are largely made from shank bones.

Sausage Casings.—Not the least important of the by-products of the cattle are the sausage casings, which, however, can best be handled in the aggregate in abattoirs, and where weasands, which form the lining of the throat, the middles, which form the larger intestines, are all properly assorted and cleansed, so as to be used for various purposes.

All the intestines are utilised for the manufacture of different kinds of sausages, and in some countries the number of different types of sausages which are made from cattle casings and beef is very great. That is an industry which seems to have developed largely on the Continent of Europe and in America, but it seems slow to move in this country.

Tripe.—The stomachs of cattle form a very valuable commodity, and are converted into tripe for edible purposes, being cleansed by hand and by machinery, and with the addition of lime. Tripe cleaning, however, is best conducted on the large scale, so that mechanical appliances may be utilised, and the item of labour reduced to a minimum. On the large scale also it goes without saying that the cleansing processes will be much more reliable than they can possibly be in the smaller way.

Pharmaceutical Preparations.—In some of the packing houses, in America especially, quite a large development has taken place in the preparation of pharmaceutical products, such as the pepsin and rennet from the stomachs of calves, and pancreatin, which is the secretion of the pancreas. The preparation of the thyroid and suprarenal glands is also extensively carried on, and the products find valuable uses in medicine.

Condemned Carcasses.—One of the results of the meat inspection of the present day is that we have a large number of carcasses condemned as being unfit for human food. In some countries it is common to destroy such portions of carcasses as may exhibit local signs of disease, reserving the remainder to be cooked and served as cooked meat for the abattoirs. This is especially common in Germany, and the cooked meat so obtained is served out in the Friebank, which is simply a shop attached to each public abattoir. In this country we do not take this view of the matter, and the condemned carcasses have necessarily to be treated so as to render them harmless, the general practice being to convert them into fat, which is used for soap-making, and a dry impalpable powder, which, as it is

Hosted by Google

sterile in itself, may be used for feeding purposes or simply as a fertiliser.

THE PICKLING OF MEATS.

There is a wide field in connection with the pickling of meats, not only in the curing or corning of beef, but in the curing of ox tongues, such as are so much in demand in this country, and which are so largely imported from abroad. Pressed beef is one of the commodities which is largely sold in this country, and its preparation is quite an art. In Scotland also the preparation of beef hams is at present a very considerable industry, and is one of the many smaller businesses in connection with the handling of a bullock which could with advantage be developed more largely.

Sausages.—There is also all over the United Kingdom quite a large trade carried out in beef sausages, and their preparation, although requiring some skill, is a comparatively easy matter, and there are not wanting text-books on the preparation of these and cognate products. It would be quite idle to attempt to give an account here of any one process in detail, as it would take much too long.

THE NECESSITY FOR ORGANISATION AND EDUCATION.

From what has been said, it will be seen that the bullock is capable of supplying a large number of products which are not manufactured at all in this country, and the reason would seem to be that there are no organised central packing houses, and even the abattoirs which exist are not so designed as to develop the specialisation of all these products from the three million cattle which we slaughter every year. It is entirely a matter of organisation and education. There would seem to be a necessity for the establishment of packing houses in this country, and there is every likelihood that such undertakings would be highly remunerative. Failing that, abattoirs could be made more profitable than they are at present, if they were so constructed as to utilise the whole of the by-products in them. I have seen an organisation of this sort at work in Hungary, where, at the leading abattoir, the whole of the by-products are appropriated by a society composed of the meat purveyors. These are manufactured into various products, and *pro rata* the profits are divided amongst the meat purveyors who compose the society. Something of that sort would be of immense advantage in the large centres of this country, but it would also be an enormous advantage if the ordinary meat purveyor could have opportunities for obtaining technical knowledge which would enable him to appreciate and to deal with these by-products in the same way as they are dealt with in other countries. It is quite idle to say that meat purveyors would not take advantage of these facilities. I have had the honour of putting that question to the test, and know that where such facilities are provided, they are taken advantage of with the greatest possible enthusiasm. The spirit of the age is towards progress, and I do not see why the meat industry should not be raised a step higher than it is; and this could easily be accomplished through our agricultural colleges, of which there are twenty-two in the United Kingdom, but whose system of education at the present moment stops at the very point where the exercise of the meat purveyor's art begins. It is a question for the Minister of Agriculture, and is also a question for the National Federation of Meat Traders' Associations, and I would commend the proposition to both, with the belief that it would be a step in the right direction.

THE FIRST INTERNATIONAL CONGRESS FOR THE PREVENTION OF INDUSTRIAL ACCIDENTS.

The first International Congress for the Prevention of Industrial Accidents was opened in the Castello Sforzesco, in Milan, on May 27th, 1912, the subsequent meetings being held in one of the King's Palaces (Villa Reale).

The proceedings were opened by an eloquent speech from Professore L. S. E. Luzzatti, late Prime Minister, and one of the honorary presidents of the Congress, who traced the growing interest taken in the care of the worker and industrial hygiene with advancing civilisation. Signor L. Pontiggia, the acting president, to whose initiative much of the recent attention given to industrial hygiene in Italy is due, gave a brief history of the Congress. He explained that the meeting was to be of an entirely informal nature, the idea being to bring together manufacturers, associations for prevention of accidents, insurance companies, and hygienic authorities to exchange views in a friendly spirit. In this way agreement could be reached as to directions in which reforms of real value to employer and employee might be made without any attempt to set up burdensome or premature legislations. Finally, Signor Battaglieri, Under-Secretary of Posts and Telegraphs, in the name of H.M. the King of Italy and the Government, declared the Congress open.

The Congress was attended by nearly 450 delegates and members. Several Governments were officially represented. Among others who were present mention may be made of—Great Britain: Mr. C. W. Bowerman, M.P. (Secretary of the

Hosted by Google

Trades Unions' Parliamentary Committee), Mr. S. Smith (representing the Home Office), and Mr. L. Gaster (delegate of the Illuminating Engineering Society). United States: Dr. W. Tolman (representing the United States Navy and Director of the Museum of Public Safety, New York). Italy: Commandant Dottore V. Magaldi, Professore A. Menozzi, and Signor F. Massarelli (general secretary). France: Monsieur J. Bocquet (Ingénieur-en-Chef de l'Association Normande pour prévenir les Accidents du Travail), Monsieur Boulisset (Inspecteur divisionnaire du Travail dans l'Industrie, Paris). Germany: Commandant Hans Breiter (German Consul in Milan). Belgium: M. Deladriere (Directeur de l'Association des Industriels, Belge). Portugal: Signor J. Magalhaes, etc.

The subjects considered at the Congress were grouped in seven sections:—

1. Handling and mounting of belting on running machinery.
2. Fencing of rolling machinery for metals, rubber, etc.
3. Ventilation arrangements to eliminate the fine dust, etc., in the cotton industry.
4. Methods of eliminating steam and vapour in dyeworks and similar factories.
5. Precautions in the design and use of centrifugal hydro-extractors (drying machinery).
6. Precautions against accidents from leakage of electricity to earth.
7. Various unclassified contributions on industrial hygiene and safety appliances.

In the first section attention was mainly concentrated on the safe handling and mounting of belts on pulleys. Several devices and suggestions were described showing how to reduce greatly the accidents from shafting and mill-gearing. The most important point was to effect the mounting of belts with perfect safety without its being necessary to stop the machinery.

In Section II. a great deal of attention was given to rolling machinery, and devices were described for preventing the possibility of an inattentive operator getting a part of the body drawn between the nips of the rollers. Proper fencing is particularly essential in the case of such machinery when used in non-engineering works (*e.g.*, in laundries, bakeries, biscuit manufacture, etc.), since the attendants in such cases, while intimately acquainted with the details of their own trade, frequently are not very conversant with mechanical appliances. A most interesting paper on this subject was read by Signor F. Massarelli, illustrated by a number of diagrams suggesting convenient methods of protection.

In Section III. quite a number of papers were presented, dealing with the importance of removing fine dust in the stripping and grinding of cotton, in carding engines and other processes used in spinning of hemp and flax. This dust is injurious to health if inhaled, causing a good deal of respiratory disease. In the well-organised cotton industry, manufacturers now recognise the value of efficient machinery for sucking in and disposing of such dust. Not only is the health of workers safeguarded, and the losses through compensation, irregular attendance, etc., reduced, but the material itself is greatly improved. In this section special mention may also be made of the contribution by M. Axel Schäffer (of the Maison F. L. Smidth & Cie, Copenhagen), giving a most instructive account of the method employed of filling sacks and barrels with cement by a special suction process.

Another matter which came up for consideration was the artificial humidification of cotton in spinning factories and weaving sheds. The importance of pure water being used for this purpose was emphasised in the papers and in the discussion which followed. It was stated that infectious diseases were apt to be propagated by contaminated water, and the desirability of fixing a standard of purity was considered. As the rules of the Congress did not permit a vote being taken on such questions, no definite decision could be framed. However, opinion on this point was quite unanimous. It is of interest to mention that such a standard has actually been embodied in the regulations which recently came into force in England, which shows how advanced the authorities in this country are on this matter.

Papers on this subject were contributed by representatives of Austria, France, Germany, Italy, Switzerland and Belgium.

In Section IV. a number of papers were read on the removal of steam in dye-works, hat and cap manufacture, silk mills, etc. The latest devices in the use of fans were described by representatives of France, Italy, and Switzerland. It was pointed out that the continual presence of steam and water-vapour in the atmosphere was distinctly prejudicial to the health of workers. It lowers the energy of the body, and thus interferes with work, and also leads to digestive troubles. It was further stated that exposure to these conditions predisposes the body to offer less resistance to the action of microbes.

In Section V. the manipulation and design of hydro-extractors was very fully discussed. The rotation of machinery at high speed in order to dry materials by centrifugal means is obviously dangerous when mechanical weaknesses are present, and some of the types described were considered imperfect in this respect. An important matter in the use of such machinery is the even distribution of the charge. Occasionally it has happened that the mass treated has become concentrated at one point in the rotating vessel, and the unequal strain set up has led to a breakdown while the apparatus was in motion, with very serious consequences. Signor Massarelli's paper in this section, dealing mainly with the use of centrifugal apparatus in sugar refineries, contained several valuable suggestions for the avoidance of such dangers, and also for automatic covers or lids for these machines.

In Section VI. considerable attention was given to safety in electrical earthing devices, official reports by delegates from Italy (Professore G. Motte), Germany (Herr C. Seidel), and France (Monsieur G.

Hosted by Google

Baigneres), being presented. Several other contributions, including a paper by Signor G. Rebora, were read in abstract. The existing regulations in England dealing with this subject have been quoted as worthy of imitation.

The papers in the Miscellaneous Section were mainly concerned with special branches of research. A useful suggestion was made by Dr. W. Tolman (United States), that it would frequently pay large works to utilise the services of a special expert in factory hygiene, whose duty it would be to keep his employers informed of all recent regulations and safety devices, and to recommend their adoption when necessary. Such an expert, called a "safety engineer," could act as a connecting link between the authorities and the owners of factories, and would be able to appreciate the views from both quarters and to smooth the way for genuine reform. This suggestion has already been made with reference to the pottery industry in England. In course of time it will, no doubt, be extended to other trades, and "safety engineers" may become a common feature in all countries. Another interesting suggestion made by Mr. Villain was that there should be agreement on some form of international danger signal. It is not suggested that this signal should supplant the regulations regarding guards, but should be used to indicate dangerous spots or passages so as to avoid accidents as much as possible.

Among the other papers in this group, special reference may be made to those dealing with the necessity for adequate illumination in factories. Mr. Gaster, a delegate of the Illuminating Engineering Society, pointed out that good light was now coming to occupy a similar position to ventilation, fresh air, and proper sanitation, and in this view he was supported by the Congress. It was desirable not only to frame some standard of the amount of illumination required for various purposes, but also to consider the proper position and distribution of lights. Instances were quoted to show how bad lighting led to accidents—a view substantiated by the recent departmental committee on accidents in this country. The Home Office in Great Britain are now paying special attention to the matter, and an important step has recently been taken in France in appointing a special committee on the hygienic aspects of lighting. The Home Secretary has promised a departmental committee on the same subject in England, and it is hoped that other nations will also take this step so as to ensure international co-operation.

A paper by Mr. V. R. Lansingh (President of the American Illuminating Engineering Society), which, in the absence of the author, was formally presented to the Congress, also advocated the claims of good illumination. Special reference was made to the work of the National Association for the Conservation of Vision in that country, and a series of illustrations were presented illustrating the proper arrangements of lights to avoid "glare" in the eyes of the worker. One point on which general agreement was expressed was the desirability of actual measurements of illumination in the factory, and it was explained that such measurement was now looked upon as quite a simple and practicable process.

It only remains to add that beside the papers read a series of visits were paid to factories in the neighbourhood which were regarded as models in their arrangements for health and safety. It is a good sign that both employers and representatives of the Governments are alive to the importance of industrial hygiene and are prepared to work together. The employer now recognises the economic importance of keeping down sickness and accidents to a minimum, and is willing to welcome suggestions as to how they can be avoided.

It is the object of these Congresses to pave the way for friendly agreement on measures which are desirable both from humanitarian and utilitarian motives. Many reforms which were originated mainly with a view to improving the lot of the worker have also proved to be well worth while as a pure matter of business. It is clearly an advantage to secure international co-operation in these matters so that manufacturers in one country may receive the benefit of improvements which have been shown to be incontestably desirable in another, so that all may work under similar conditions and in fair competition.

The name of the acting president of the Congress, Signor L. Pontiggia, deserves to be remembered and connected with the initiation of this movement for improving industrial health and safety, and acknowledgement should also be made of the services of the capable general secretary, Signor F. Massarelli. It may be added that Italy has for some years taken a conspicuous part in this work, and the special institute devoted to industrial hygiene in Milan under the care of Professore Devoto, is the first of its kind in existence.

The next Congress is to take place in 1915 at Paris, and no doubt by that time there will be important advances to record.

L. GASTER.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

The Condition of Trade.—In respect of the influx of new business the markets vary, but in one vital particular the industries of the textile group are much alike. They have in general plenty of work in hand, and so are above the necessities of a moment. Makers are not immediately able to get the advances they would like, but their affairs in general are healthy. Manchester is industriously recouping itself for the series of lean years. Bradford finds some life still left in its protracted boom. Dundee is very firm and able to command high prices for fine yarn. Belfast is entrenched securely behind walls of orders for linen cloth. Even the trades which are in between seasons are not described as dull, and the business in woollens

Hosted by Google

called by the name of shoddy, is especially lively. In all, reports from British centres contrast favourably with those from any manufacturing country, and the financial results recorded are almost uniformly good. The textile industries do not invariably flourish in harmony, for some of the parts are mutually antagonistic, but they come very near to perfect unison at the present time.

Artificial Cotton.—As one of the cheapest of fibres, cotton presents relatively a slender front to the inventor of artificial substitutes. The sale for a satisfactory substitute might be taken as infinitely large, but with Middling American at something under 7*d.* per lb., the available margin for working expenses is manifestly restricted. Cotton of this quality can profitably be grown for less than the market price of the present, and it has sold for less than half the money. Even assuming that the cotton produced by chemical or other means served the purpose of fine long-staple material, worth one shilling, it is still evident that a practicable process would have to employ an inexpensive base and reagents. If it be asked what such a process would be worth, there is the evidence in a Paris police-court case for an answer. Signor Crespi, manufacturer and Deputy of Milan, had agreed with a Manchester firm to sell the patents for a process of making fine cotton for £400,000. The arrangement was presumably provisional, and now that one of the inventors has been convicted of supplying beforehand the cotton that he professed to manufacture, it is to be presumed that little more will be heard of the business. The reward mentioned may be large enough to induce others to persevere in the face of the economic difficulty. Hitherto nothing—natural or artificial—has taken cotton's place or given substantial promise of doing so. There have been attempts to foist rivals into prominence, and presumably most persons have heard of the extravagant claims made on behalf of ramie. But cotton is cheap to work as well as to grow, and one can buy, manufacture and sell cotton yarn for as little as it costs simply to work ramie. With Middling cotton quoted 6·60*d.*, yarn is quoted $9\frac{9}{16}d.$ for 32's weft, and $10\frac{1}{16}d.$ for 32's twist. The prices give an idea of the economy of the operation. Some American figures secretly obtained in Lancashire by agents of the Tariff Board may not be unchallengable on the score of accuracy, but they go to show that the total cost of converting raw cotton into yarn measuring thirty times 840 yards per lb., is from $1\frac{1}{4}d.$ to $1\frac{3}{8}d.$ per lb., in seven Lancashire mills. A cost of 1·749*d.* per lb. is given in Mr. Winterbottom's "Cotton Calculations," as the average of the Oldham district.

Ramie.—Except in conjunction with incandescent gas-mantles the name of ramie is little heard in these times. For reasons probably connected with its high absorptive properties ramie answers admirably for this purpose. After the match has been applied to the impregnated mantle and the carbonaceous structure has been removed, a strong crust of luminous metallic salts remains. As a single pound of ramie yarn is computed to make some five or six gross of mantles, it is obvious that the aggregate weight of raw material required to satisfy the lighting industry is relatively small. Even in this field ramie has a more or less serious rival in moulded mantles made by dissolving and precipitating cellulose in a manner akin to that by which artificial silk is made. Apart from a narrowly limited range of uses ramie remains easily the most consistent disappointment in the whole family of textile fibres. More money has been sunk in its development to less purpose than in anything that has engaged English attention. According to estimates, which nobody contradicts, some thirty millions have been lost in ramie by planters and manufacturers during fifty years. One German undertaking, succeeding where virtually everyone else has failed, pays good and regular dividends out of ramie manufacture, but otherwise, the industrial history is a story of unrelieved disaster.

Huddersfield Worsted.—The projected visit of the King to one of the most famous worsted cloth mills in the world may be expected to have some influence on the public. Wearers of suits accept their Huddersfield worsteds as a matter of course, usually without inquiring how or where they came into being, and without the remotest conception of the pains that have been taken to make the cloth perfect. It is the special function of the high-class Huddersfield firms to clothe the West-ends of most capitals with fabrics for dress-suits, the fancy trouserings which tailors call "cashmere," and the unimpeachably neat greys which are generally worn in the absence of Scotch tweeds. Huddersfield has some assistance from surrounding neighbourhoods, and from the West of England in this task, but all that can be done by the best designers, weavers, and finishers using the best materials at command, is done in Huddersfield. More is spent there in producing new worsted patterns than in the whole of the rest of the world, and if fault can be found it is that the goods are faultily faultless, too austerely reticent in colouring, and exquisite in woven effect. Periodically there is a reaction from the monotony of irreproachable style, and the fashionable turn to the bolder and rougher tweeds. The ordinary wearer never discovers that it has taken a combination of six shades of grey to produce the particular tone prevailing in his suit, and has no suspicion that anybody spent days in working out an infinitude of permutations and combinations to arrive at the ultimate result. Any notion that the production of a single inch involves more than one hundred, and perhaps over two hundred passages of the shuttle is, of course, absent. In the instance of a blue cloth of an uncommonly fine quality made near Huddersfield, seven pounds of the finest Australian wool has to be bought in order to find a single pound of wool fine enough for the purpose.

Hosted by Google

Colne Valley Tweeds.—The accounts do not make it clear that His Majesty is to enter any of the very different mills which exist to feed the machinery of the wholesale clothing factories. Huddersfield stands at the confluence of the Holme and Colne Valleys, and along the steep sides of the latter are the mills producing the famed Colne Valley tweeds. It is for smartness and insuperable cheapness that these goods are renowned, and it is due to Colne Valley skill in imitating the appearance of high-priced tweeds that Scotch and Irish tweeds are seldom fashionable wear for long amongst ladies. The mistress finds that the servant has bought for a very few shillings a fair replica of a costume for which she paid nearly as many guineas. The larger part of the goods are for men's wear, and many of them are overcoatings. They are light or dark, soft or cheviot-like in handle, according to the seasons, and at present many are slavishly faithful copies of the well-known Donegal cloths. They range in wholesale price from 1*s*. 4*d*. to 2*s*. 9*d*. a yard, the cheaper ones contain cotton, and wear the better for it, and the higher qualities contain a good deal of stocking wool. The chief raw material is pulled hosiery, costing 4*d*. or 5*d*. a pound, and the virgin wool used is largely "locks and pieces" from the floors of Colonial shearing sheds. Between them, the mills use any and every sort of wool waste, and have no superiors in their own line in turning unpromising material to advantage. The goods appear in every cheap clothier's windows throughout the British Isles, and they go in quantity to Canada, Australia, South America, the East and the Continent. Some German goods approach them in value, but the Colne Valley is unbeaten or unbeatable. Its mills run night and day for long periods together, and no reviling of its goods as shoddy disposes of the fact that it gives people what they want at the prices they can pay.

Spun Silk.—A remarkable change has come over the English silk-spinning industry within the last ten years. In that space of time the trade has advanced from the depths of depression to a sound state of prosperity, despite the decay of that which was its main support. No statistics record the gradual contraction of the demand for white yarn, and the substitution of a new demand for tussah silk. The change is none the less a fact, and those with opportunities for forming an accurate judgment estimate that four times more tussah is now being spun than in the first years of the century. The trade in China and Italian qualities has been filched away apparently by mercerised cotton and lustracellulose. Simultaneously there has grown up a convenient demand for yarn spun from the waste formed in reeling the brown cocoons of the oak-feeding silkworm. The taste for tussah summer clothing is apparent on all hands, although it is to some extent met by cotton and flax and cotton imitations. Again, there is the fashion for seal plushes in which the pile is tussah silk, and there is a certain trade in tussah cloth for the wear of miners in hot climates. The very by-products of the tussah industry have been commanding a high price, and the decision applying a prohibitively high duty to tussah noils of the longer sorts entering the United States has had comparatively little effect on prices. The Americans were mixing these noils with wool to make a fleecy face upon overcoatings. There is now a good consumption of the noils upon the Continent, where they are recombed and spun. Should misfortune overtake the business in tussah yarn a difficult predicament might arise, in course of which spinners might have to take more seriously into consideration the advisability of adopting Continental methods of work. Proceeding by the "schappe" or fermentation process, which does not remove the whole of the silk gum, the Continental spinner is enabled to produce a yarn of even surface from short, and consequently cheap, material, and it is a simple fact that the Italians are selling single yarn in the English market with which yarns made by the traditional English method are entirely unfitted to compete.

NOTES ON BOOKS.

Répertoire de Couleurs pour aider à la Détermination des Couleurs des Fruits, des Feuillages, et des Fleurs. Publié par la Société Française des Chrysanthémistes. London: The Royal Horticultural Society.

The necessity for a standard for the discrimination of colours has long been felt, and at different times attempts have been made to provide such a standard. In 1891, the council of the Society of Arts appointed a committee to consider the practicability of formulating a standard of colour for industrial purposes. This committee, after some discussion, decided on a preliminary or provisional list of names for standard colours, and selected a series of tints which they considered were represented by those names. It was proposed to prepare, by means of the colour-patch system invented by Sir William Abney, a formula for each of these tints, by means of which a patch of light, accurately representing the tint, could be reproduced at any time or place. There is no doubt that if such a standard could be successfully established, and if a sufficient number of different hues could be thus named and standardised, such a standard would be of very great value for many purposes. But the labour of examining a sufficient number of different colours, and of determining with accuracy the formula for each colour, would be very great, and, unfortunately, the excellent intentions of the committee were never carried into effect.

Some time ago, the French Chrysanthemum Society undertook to discriminate and to name a number of different colours, with the idea of

Hosted by Google

providing gardeners and florists with the means of recognising and discriminating the precise colour of any possible flower. The French Society, perhaps wisely, did not attempt anything like a scientific classification, but were satisfied to select a number of colours, to give them names, and to reproduce, by printing upon paper the colours they had selected. It is obvious that such a standard is very far from being an ideal one. Colour prints upon paper fade and change, and there is no doubt that in a few years the samples provided by the French Society will have altered considerably in character. There are also other questions to be considered, such as the difference in colours resulting from difference in texture of the coloured surfaces, and also the different appearance presented by identical colours seen upon a background of the same or of a different tint. But when scientific accuracy is not sought, and all that is wanted is a means of approximately identifying different hues, there can be no question whatever that a list such as has been provided by the work of the French Society is of very great value. Recognising this fact, the Royal Horticultural Society have obtained a stock of the prints published by the French Chrysanthemum Society, and are offering them at the moderate price of 14*s*. 6*d*. to their Fellows.

There appear to be altogether 365 different colours which have been selected, and to each of these a name, more or less appropriate, has been given. Each of these colours is printed in four shades, making in all 1460. The names selected are purely arbitrary, and it would be easy to criticise a good many of them. But this, perhaps, does not very much matter, as each colour or shade has a number, and can be at once identified. The colour-names originally selected were in French, but corresponding names in German, English, Spanish and Italian are also supplied.

THE PAINTERS' POCKET-BOOK. By Arthur Seymour Jennings. London: The Trade Papers Publishing Co., Ltd. 3*s*. net.

The public appreciation of this practical guide for painters and decorators is amply proved by the fact that it has now reached its third edition. In its present form it is much enlarged, the number of its pages having been increased from 156 to 252; but it is still so handy that it can easily be carried in the pocket. In spite of its convenient size, however, it contains an immense amount of information. After dealing with tests for pigments, it describes how to measure painters' work; this is followed by a long section on prices, and another on defects in painting and the remedies therefor; and the book concludes with a number of tables of wages, prices, etc., which should be of daily use to the painter and decorator. Not the least valuable part is a concise dictionary of terms used in painting, building, architecture, art, applied chemistry, etc. Many of these terms are explained by illustrations, most of which are useful, but in some cases they are too small to be of much service: *e.g.*, no one who did not know beforehand what a raised panel was, would be able to deduce the information from the picture. To some of the illustrations, again, there is no reference in the text; *e.g.*, the word "pinnicle." This, doubtless, under its more usual spelling, is sufficiently familiar to require little explanation, but as much cannot be said of the word "swag," nor does the illustration do much to lighten the darkness of the uninitiated. These, however, are but very small points, and they are only mentioned in order that they may be corrected in the next edition. The bulk of the book is written by Mr. A. S. Jennings, the well-known editor of *The Decorator*. There are also special contributions by Mr. Noel Heaton, who recently delivered before the Royal Society of Arts a course of Cantor lectures on "The Materials and Methods of Decorative Painting," and Mr. Charles Harrison, Lecturer on Painters' Oils, Colours and Varnishes, at the Borough Polytechnic.

GENERAL NOTES.

NATIONAL CONGRESS ON REFRIGERATION AT TOULOUSE.—The second National Congress on Refrigeration will be held at Toulouse on the 23rd, 24th and 25th September next. Organised by the Association Française du Froid, it will, as its title implies, embrace everything that relates to refrigeration and the use of artificial cold in agricultural and other industries. Excursions will be made by the members of the Congress in order to visit some of the principal centres of wine production in the south of France, where the latest applications of refrigeration in connection with this industry are in use. Another excursion will be made to Roquefort, where artificial cold is successfully used in the manufacture of the celebrated cheese of that name. A visit will also be made to the agricultural exhibition at Bourges, where, under the auspices of the Automobile Club a special section for freezing apparatus will be opened.

NUMBER OF BICYCLES IN FRANCE, 1911.—The number of bicycles in France appears to be on the increase, judging from the latest returns for 1911, which gives a total of 3,009,626 as compared with 2,697,406 of the previous year. The total revenue from the tax on bicycles last year amounted to upwards of nine millions of francs (£360,000), or about half a million francs more than in 1910. The ten departments having the greatest number of bicycles last year were those of the Seine, with 309,759; Nord, 159,656; Seine-et-Oise, 97,271; Gironde, 75,390; Pas-de-Calais, 70,610; Seine-Inférieure, 62,997; Maine-et-Loire, 60,265; Saône-et-Loire, 58,595; Seine-et-Marne, 55,594; Loiret, 54,510. The department with the smallest number was that of Lozère, with only 2,920 cycles.

NOTICES.

CHAIRMANSHIP OF COUNCIL.

On Monday, the 8th inst., at their first meeting, the Council re-elected LORD SANDERSON, G.C.B., K.C.M.G., Chairman for the ensuing year.

PRACTICAL EXAMINATIONS IN MUSIC.

The Practical Examinations in Music were not concluded this year until the 3rd inst., too late for the results to be included in the Report of the Council. They lasted for eight days.

The examinations were conducted by Dr. Ernest Walker, M.A., and Mr. Burnham Horner.

The system of examination was the same as that for recent years. For instrumental music certain standards are given, and candidates are asked to select for themselves which of these standards they choose to be examined in. The standards range from easy to very difficult music. For each standard a list of music is given for study, and from this list candidates select the pieces they will sing or play. Candidates are expected to play or sing the pieces which they have prepared, to play or sing a piece, or portion of a piece, at sight, and to play certain scales.

In all, 300 candidates entered, and of these 296 were examined, an increase of 13 as compared with last year. There were 220 passes and 76 failures.

The following were the subjects taken up:—Piano, singing, violin and violoncello. 239 entered for the piano, 176 of whom passed; 45 entered for the violin, of whom 35 passed; 2 entered for the violoncello, 1 of whom passed; 10 entered for singing, of whom 8 passed.

The examiners report that the average quality of the pianoforte playing in the less advanced standards was better than last year, particularly as regards touch. In the other departments of the examination there was no noticeable change. Several of the candidates were ill advised in attempting standards which were as yet beyond their technical and interpretative powers.

THE ROYAL SOCIETY OF ARTS.*

By SIR HENRY TRUEMAN WOOD, M.A.,
Secretary of the Society.

IX.—THE SOCIETY AND FORESTRY.
(1758–1835.)

As far back as the Restoration complaints had been rife of the lack of timber. Wood was almost the only fuel. It was one of the principal materials for construction on land, and the only one available for naval purposes. The forests which once covered the country had been cut down, and the timber used for a thousand purposes, of which the most important were shipbuilding and iron-founding. The places where the iron manufacture was located were decided, not as now by the existence of coal, but by the neighbourhood of forests. Sussex and the Forest of Dean were the chief centres of the iron trade, not so much because of the abundance of iron ore, but because of the abundance of wood. Sheffield became the chief seat of the cutlery business because it was surrounded by forests; and as the wood was used or burnt no efforts were made to replace it.

In or about 1662 the Navy Office, alarmed at the increasing lack of timber for naval purposes, applied for advice to the Royal Society, who

* The previous articles of the series appeared in the *Journals* of June 9th and 16th, September 22nd and 29th, and November 3rd, 1911, January 12th, 19th and 26th, April 5th, and June 14th and 21st, 1912.

Hosted by Google

passed on to John Evelyn the questions they had been asked. The result of his investigations was the well-known book, "Sylva, or a Discourse of Forest Trees and the Propagation of Timber in His Majesty's Dominions."* In it Evelyn appealed to the landowners to improve their forests and woods, and, paraphrasing the words of Nehemiah, he cried, "Let us arise then and plant." "To you princes, dukes, earls, lords, knights, and gentlemen, noble patriots (as most concerned), I speak to encourage and animate a work so glorious, so necessary." It is doubtful whether this remarkable book, which has become an English classic, had any very great practical or permanent effect, though the author was able to boast that "many millions of timber trees have been propagated and planted at the instigation and by the sole direction of this work."

At all events, things were no better a century after Evelyn's time, though the use of "sea-coal" for fuel had increased, and it was applied for various manufacturing purposes. Iron, however, still had to be made with charcoal, since it was only about 1730 or 1735 that Abraham Darby first succeeded in employing coke for the purpose, and about 1750 that he had established the manufacture on a commercial basis. For many other manufacturing purposes, coal, with its sulphurous fumes, was not considered suitable, and nearly all over the country wood was still the only domestic fuel. Not only were the trees cut down, but they were either pollarded or stripped of their branches. Arthur Young, in his "Farmer's Letters," says that in many parts of the country the result of this practice had been to convert the trees into "May-poles."

Attempts had been made by legislation to limit the use of wood for fuel, but apparently there had been no serious efforts to replace the stock of timber by acting on the principles laid down by Evelyn, until the Society of Arts took up the question.

The first suggestion came from Mr. Henry Baker, who, according to the minutes of the meeting of March 26th, 1755, presented to the Society from the author, Mr. Edward Wade, "a quarto pamphlet published by him to promote the planting of timber trees in the common and waste ground all over the kingdom for the supply of the Navy, the employment and advantage of the poor as well as the ornamenting the nation." This led to the inclusion in the 1758 prize list of three premiums for tree-planting. A gold medal and two silver medals were offered for sowing the greatest quantity of land with acorns (five acres at least), four bushels to the acre. Similar premiums were also offered for planting Spanish chestnuts, elm, and Scotch fir. In 1759 the same prizes were offered, with the addition of similar awards for Weymouth pine, "being the properest sort for masts." As time went on various additions were made to the list, and the conditions were varied, but not very widely. Eventually the list included besides oaks, which were to be planted as well as raised from acorns, and the trees above mentioned, red Virginia cedar, spruce fir, silver fir, larch, Norfolk willow, alder, red willow, ash, Lombardy poplar, elm and walnut. At one time, about 1795, a special prize was offered for oak trees in "compass forms" for shipbuilding, but this elicited no response, and the offer was dropped.

The first award was in 1758, when a gold medal was given to the Duke of Beaufort for sowing twenty-three acres in Hawksbury, Gloucestershire, with acorns.* In 1761 the Duke of Bedford received a silver medal for sowing eleven acres with acorns at Woburn, and in 1763 a second similar medal for 16,000 Scotch firs planted at Millbrook, Bedfordshire. In 1761 Earl Winterton had a gold medal for sowing twenty acres near Plaistow with acorns. Lord Winterton also received another gold medal in 1767 for planting 2,000 elms in Ash Park, Sussex, and two more in 1776—one for sowing acorns and the other for planting Lombardy poplars. In 1763 the Earl of Portsmouth had a gold medal for planting 6,100 small-leaved or English elms. After this date the prizes become more numerous, and the following awards were made to various noblemen for plantations on their estates: 1766, silver medal to Lord Scarsdale for planting Scotch firs; 1767, gold medal to Viscount Turnour for Spanish chestnuts, gold medal to the Earl of Moray for planting 7,646,000 oaks, firs and other trees; 1779, gold medal to Lord Paget for sowing acorns, and silver medal to the Earl of Donegal for planting oaks; 1784, gold medal to the Earl of Upper Ossory for his plantations (not specified); 1788, gold medal to the Earl of Fife

* The "discourse" was "delivered" to the Royal Society October 15th, 1662, and the complete book was first published in 1664.

* The entries up to 1783 are taken from four sources: the "Register of Premiums," 1778; Dossie's "Memoirs of Agriculture," &c., Vol. III., 1782; the list in Vol. II. of the *Transactions*, 1784; and a list in Vol. XLIX. of the *Transactions*, part ii. p. 1. These lists do not always agree. From 1784 on we have the annual prize lists in each volume of the *Transactions*.

Hosted by Google

for his plantations in Scotland. The same nobleman got a second gold medal in 1803 for planting forest trees. In 1797 a gold medal was given to Lord Brownlow for planting osiers, but this was a special offer, quite apart from the prizes for raising timber.* Two years before, Lord Brownlow had a grant of £20 for the same thing, which was a very unusual thing in the case of noblemen, since members of the peerage were only considered entitled to honorary rewards. In 1800 the Marquis of Titchfield had a gold medal for sowing acorns; in 1803 Viscount Newark received a gold medal for planting oaks; in 1805 the Earl of Breadalbane had a silver medal for firs. In 1808 the Earl of Mansfield had a gold medal for oaks. A gold medal was presented to the Duchess of Rutland in 1816, but this was for ascertaining the best method of raising oaks, and was not a prize for planting. In 1820 the Duke of Devonshire received a gold medal for planting forest trees. The last award for plantations to a nobleman was the gold medal given to Lord Newborough in 1828 for planting forest trees.

Richard Watson, who was Bishop of Llandaff from 1782 to 1816, received three gold medals from the Society; in 1788 for larch, in 1789 for ash, and in 1808 for larch. All his plantations were on an estate which he inherited in 1786.

The awards to other landowners are too numerous to set out in detail, but some may be mentioned, on account of their comparative importance, or because of the personality of the recipient.

In 1759, a gold medal was awarded to Dennis Rolle, of Hudscot, Southmolton, for sowing about twenty-five acres with acorns, and three silver medals were given to Philip Carteret Webb, John Berney and T. Drew, for sowing smaller areas. Dennis Rolle received a second gold medal in 1761 for planting over 100,000 Scotch firs. In 1763, four gold medals in all and two silver were awarded for elms, chestnuts and fir.

In 1764 Robert Fenwick, of Lemington, Northumberland, had a gold medal for 104,000 Scotch firs. In 1765 he had a second for another 102,000, and in 1766 a third for yet another 100,000, 306,000 in all.

William Beckford, the author of "Vathek," in 1769 received a gold medal for planting 61,800 Scotch firs at Fonthill, the celebrated estate where he ruined himself by his lavish expenditure on fantastic decoration.

Richard Muilman Trench Chiswell, of Debden Hall, Essex, had a gold medal in 1776 for planting Lombardy poplars, and two gold medals, in 1777 and 1778, for planting elms. His name was originally Muilman, and he changed it on succeeding to the Debden Hall estate. He was an antiquary, and wrote on the history of Essex.

Thomas White, of West Retford, Notts, received six gold medals in 1778 for his plantations of poplar, larch, Scotch fir, occidental plane tree, spruce fir, and silver fir. He also received two gold medals in 1779 for Norfolk willow and ash, one in 1785 for elm, one in 1786 for alders, and a silver medal in 1788 for oaks, making in all ten gold medals and one silver medal.

In 1778 a gold medal was awarded to William Mellish, of Blythe, Notts, for planting 101,600 spruce firs, and in 1780 a second medal for 475,000 larches.

Lewis Majendie, of Hedingham Castle, Essex, received four gold medals for planting oaks, chestnuts and ash (two) in 1792, 1794 and 1797.

The most extensive plantations were those made by Colonel Thomas Johnes, of Hafod, Cardiganshire, a man of considerable reputation in his time. He was Lord Lieutenant of Cardiganshire, and from 1774 to 1816 he represented a Welsh constituency. He was well known as a book collector and as the translator of Froissart, Monstrelet, and other chroniclers. Between 1795 and 1801 he planted 2,065,000 trees, of which number 1,200,000 were larches. Besides this, fifty-five acres of land were sown with acorns, or planted with oaks, and it was subsequently stated that he had raised 922,000 oaks. He received altogether six gold medals from the Society, in 1800, 1801, 1802, 1805, 1810 and 1813. A special account of his plantations is given in the preface to Vol. XIV. of the *Transactions* (p. x.).

John Christian Curwen, M.P., of Workington Hall, Cumberland, received four gold medals, in 1797, 1802, 1804, and 1809, for sowing acorns, and for planting larch (two) and timber trees. In 1801 and 1802 he planted 814,000 trees. He was a member of the Society from 1798 to 1827, and a Vice-President from 1809. Besides these awards for planting, he received seven gold medals and one silver for cultivating wheat, beans, carrots, cabbages and potatoes, for draining and improving land, and for feeding cattle. In all he received eleven gold medals from the Society, which must certainly be the largest number presented to any single individual. He contributed numerous papers to the *Transactions*, and also published a good

* See *Journal*, January 26th, p. 271.

Hosted by Google

deal on agricultural matters, and on the condition of the labouring classes. According to a statement made by himself, it was due to the Society that he first took up farming.

Dr. William Makepeace Thackeray, of Chester, received a gold medal in 1809 for extensive plantations of ash, beech, chestnut, elm, and other forest trees, and another one in 1819 for planting 188 acres with forest trees. He was a first cousin of Richmond Thackeray, the father of the novelist. The plantations, according to the account he gave of his work in the *Transactions*, were made on property in Denbigh and Merioneth, belonging to his stepson, J. M. Jones, for whom he was trustee.

Dr. Henry Ainslie received a silver medal in 1803 for planting timber trees, and a gold medal in 1812 for the same. He was a distinguished physician, Senior Wrangler, and a Fellow of Pembroke.

Charles Fyshe Palmer, M.P., of Oakingham, Berks, received two gold medals for forest trees (893,000) and oaks, and a silver one for sowing acorns—all in 1821. Before this, in 1819, he had a silver medal for planting 115 acres with forest trees.

The last award for tree-planting was in 1835, when a gold medal was given to Edward Rogers, of Stanage Park, Radnor, for plantations carried on from 1799 to 1831 by Mr. Rogers and his father. The number of trees planted was about 700,000 (*Transactions*, Vol. L. part ii. p. 1).

In all 127 gold medals and forty silver medals, besides certain pecuniary grants amounting to about £200, were given by the Society for arboriculture. Nearly all these were awarded in the period from 1758 to 1821. After 1821 there were very few awards, only seven in all. The offer of prizes was continued down to 1846, but was not renewed after that year.

It is impossible to state with exactitude the number of trees planted which these awards represent, for although, in some cases, the particulars are given in the records of the Society with extraordinary precision, in others such phrases as "extensive plantations" are used; but at the very lowest estimate this number must have considerably exceeded fifty million, of which some twenty million were firs and larches, and some fifteen million oaks.

On the whole, it may certainly be said that the attempt was extremely successful, thousands of acres were planted, and, as a practical result, the supply of timber was, to a certain extent, renewed. Many of the woods throughout the country owe their present existence to the initiative of the Society of Arts.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

THE MEAT INDUSTRY.

By Loudon M. Douglas, F.R.S.E.,
Technical Adviser on Animal Industries.

Lecture II.—Delivered February 12th, 1912.

The Sheep and its Products.

We now come to consider the sheep from the point of view of its use in animal industries, and at the outset it will be well to remember that there are many varieties of the sheep in different countries. In the United Kingdom alone there are some thirty-two different kinds, divided up generally into the long-woolled, short-woolled, and mountain breeds, each one having its own particular recommendation; but from the classification indicated, it will be evident that the particular characteristic of the sheep is its fleece, and that, in the development of this particular animal, more regard has been paid to the wool product than to the carcass. It will be rather difficult to make a definite classification in the breeds of sheep, as so many of the existing types are merely the result of selection and cross-breeding. The type which has undoubtedly influenced the various races to the greatest extent is the merino, which originated in Spain, and which was introduced into the United Kingdom from that country about the year 1786. The merino has been successfully crossed with many English breeds, and the immediate effect has been an addition to the weight of the carcass. It seems to be well established, however, that it is difficult to get a large produce of wool together with a large carcass. The protein of the food is utilised either for the production of mutton or the production of wool, and the plan of Nature appears to allow only the one characteristic or the other to predominate.

Statistics.

It is of interest to observe that the distribution of the sheep throughout the world is totally different from the distribution of cattle. Thus we have:—

* In Europe	160,036,801
In North America	67,771,781
In Central and South America	97,723,396
In Asia	45,758,478
In Australasia	109,492,319
In Africa (about)	60,000,000
	540,782,775

* "Statistique des Superficies Cultivées, de la Production Végétale et du Bétail," Institut International D'Agriculture, Rome, 1910.

Hosted by Google

A notable feature of these figures is that in Australasia there are over 109 million sheep as compared with 12 million cattle, and in Central and South America there are over 97 million sheep as compared with 43 million cattle, and, as we shall see, these particular countries are our principal sources of supply for the mutton which is imported into this country from overseas.

The imports of mutton and lamb into the United Kingdom reached a total of 594,719 tons, which is equivalent to 12,960,383 carcasses, and these come from Australia, New Zealand, Argentina, Uruguay, and Patagonia; and the fact that we are dependent on these countries for such huge supplies is very remarkable in itself, seeing that the produce is derived in the first instance from British-bred animals which from time to time have been imported there.

The home supply of sheep is fairly constant, the figures for 1911 being 30,479,807,* and it is computed that out of that number we slaughter about 40 per cent. every year. We are therefore able to compute the home supply of mutton and lamb at 326,570 tons, as compared with a total import of 268,149 tons. In carrying on this business in overseas countries, there are fifty-seven freezing works in Australasia, and eleven establishments of a similar character in South America, and their total produce, with a very slight deduction, which is sent to other countries, is shipped to the United Kingdom, there being some 205 cold storage steamers engaged in this trade,† and while the imported produce for 1911 was somewhat smaller than in the former year of 1910, there is every reason to believe that the imports in the future will be larger still, owing to the fact that the ratio of sheep produced in the United Kingdom to the population is constantly on the decline, and the demand for mutton is constantly on the increase. In 1871 the total of the flocks in the United Kingdom exceeded the population by 4 per cent. In 1881 there were 827 sheep to every thousand inhabitants, and in 1910 the number had fallen to 659 per thousand.‡

Mutton.

Mutton is derived mostly from young sheep of either sex. Much attention has been paid of late years to the characteristics which the carcass should present, and breeders have endeavoured to produce carcasses which will primarily have a small proportion of bone to flesh, and with a small amount of fat.

In judging a carcass, it may be said that the process should be, first of all, to divide it transversely through the middle, so as to expose what is known as the "eye" of the chop, and the principal features to be noted will be the colour, then the thickness of the lean, after that the firmness of the fat. In so far as the legs of mutton are concerned, these should be plump, and form an almost straight line from thigh to thigh. V-shaped legs are of an inferior quality, and will most likely present other features of bad breeding.* As a matter of fact, the question of judging the quality of mutton has been only within recent years reduced to something like a system, and a standard has been set up which appears to meet the requirements of the case.†

Standard of Excellence for Judging Carcasses of Mutton and Lambs.

1. Dressing of carcass	10
2. Colour, general appearance of carcasses, and firmness of flesh	10
3. Proportion of meat to bone	15
On splitting the carcass and dividing it transversely, the following points are to be noted:—	
4. Colour, texture, and thickness	10
5. Plumpness of legs of mutton	20
6. "Eye" of the chops and thickness of loin .	25
7. Fleshiness of forequarters	10
Total	100

It may be mentioned that the age of slaughter for sheep varies from two to three months to two years, but a ripe animal may be put down as being twelve months old. The weight of the carcasses varies from 45 to 100 lbs., the average of imported carcasses being about 56 lbs., and it is a remarkable feature of mutton that, if hung for some little time in a fresh cool atmosphere, it becomes much more palatable and tender.

"The process of mutton making," says one writer on the subject,‡ "is thoroughly English. The internal formation of fat is the first process in all the English sheep. A network of fat is first formed which envelops the intestines, and another mass accumulates on the kidneys. Thus it begins to be deposited on the rump, and the first symptoms are the sides of the rump rising, so that the backbone cannot be felt. They begin to be cloven. This progresses gradually on the back until the backbone is lost, and instead of the protuberant bones there is a crevice along the line of the back to the shoulder, or possibly to the juncture of the neck. Then it begins to

be accumulated on the sides, and proceeds towards the flanks, and forms on the breasts, shoulders, and brisket, thus showing how gradually the whole tendencies of the sheep in all climes are brought out to make a fat-mutton English, or rather British, sheep. When all this is accomplished, the sheep is fat or prime."

compared with 1,281,707 in 1911. A somewhat similar increase has taken place in New Zealand and South America, and these developments have become possible only through the use of mechanical cooling appliances. In fact, it is to the refrigerating machine that we are indebted for many accessions to the food supplies of this

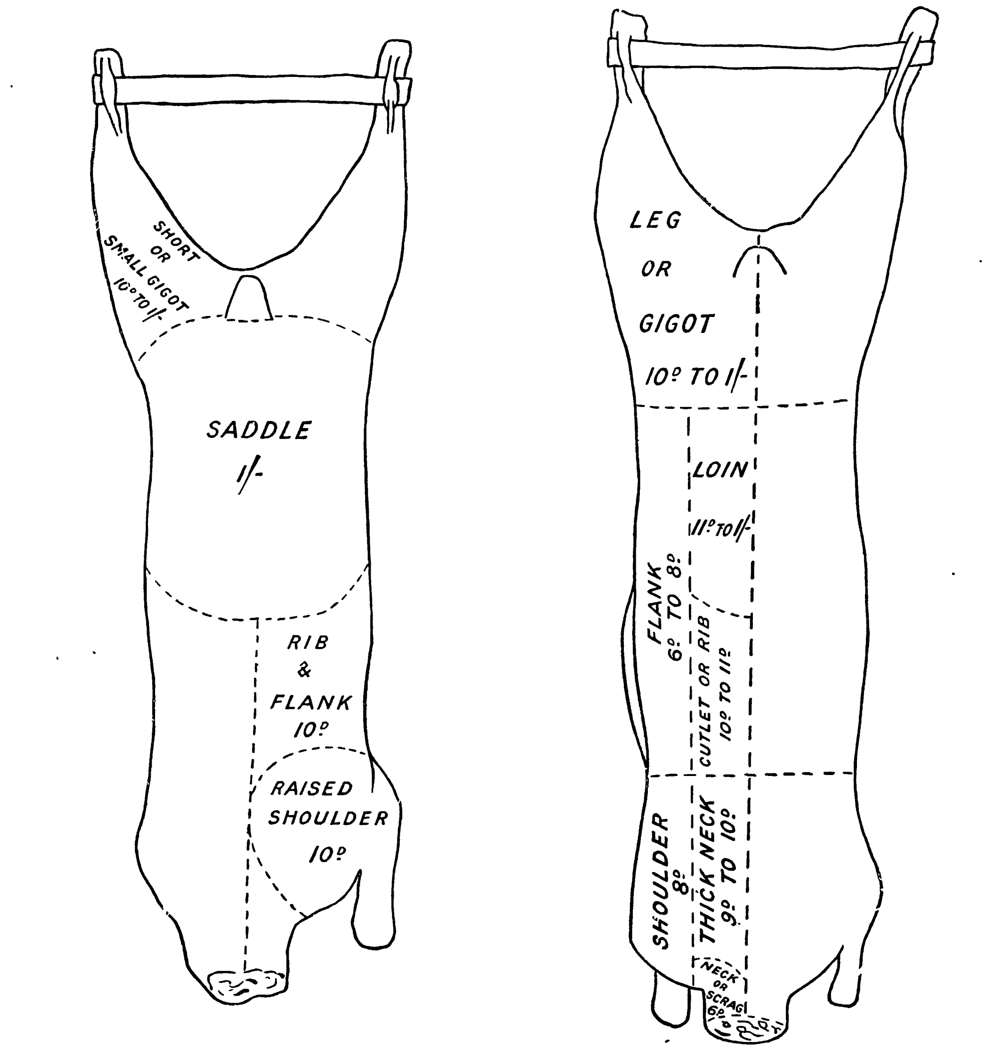

FIG. 9.—DIAGRAMS OF CARCASSES OF MUTTON.

Illustrating the various cuts and different methods of cutting up, as also the average prices in the United Kingdom.

THE FROZEN MUTTON INDUSTRY.

In discussing the question of the import of mutton from foreign countries, it will be desirable to recall that this trade has grown within comparatively recent times. It will be remembered that in the year 1880 the shipment of mutton carcasses from Australia numbered only 400, as

country. Its influence has, within the short time of a generation, annihilated distance and made it possible to have fresh food from the furthest colony delivered anywhere within the United Kingdom. It was in 1879 that the first cold-air refrigerating machine was installed on a vessel called the "Strathleven," which brought

Hosted by Google

the first cargo of frozen meat from Australia to London, and, as we have already seen, there are now 205 vessels engaged in this trade. The principle of refrigeration, as applied to the storing of mutton, is now well understood, and it would seem to be the general opinion that it is undesirable to bring mutton from a distant country except in the frozen condition, or at a temperature some 12° below freezing-point, which means, of course, that a certain amount of rupturing of the cells takes place owing to expansion, and a consequent loss of meat juices supervenes on the thawing out. If, therefore, the chilling at a temperature of about 28° F. could be adapted to the handling of mutton, it would be an immense advantage from the economic point of view. It would hardly be possible to enter into the details of this question here; suffice it to say that it is one which deserves the best attention of refrigerating experts in this country and in the overseas countries referred to.

By-Products.

Wool.—So far, we have dealt entirely with the meat industry point of view of the sheep, and we may now with advantage consider what are the other products available. Many of the 146 products derivable from a bullock are also obtainable from a sheep, such as blood, horns, fat, sausage casings, pharmaceutical preparations, sausages, bones, fertiliser, etc., but the principal product is the wool, which, as we have said, is considered in many countries to be the chief product. This is especially so in Australia, where the merino predominates over all other breeds because of its wool-producing characteristic.* With regard to the Argentina, there has been a considerable modification in the breeds, owing to the introduction of the Lincoln type about 1845, which has been followed in later years by Leicesters and Romney Marsh types. Wool, however, is the main product to the sheep farmer of the Argentine, and it is curious to read that, so recently as 1843, the carcasses of sheep were boiled down entire and converted into fat, bones, and glue. As we have seen, that condition of things has been altered since 1883, and a steadily increasing exporting mutton trade is the result. Wool is one of the products which has become a necessity amongst civilised nations, and the fabrics which are made from it, so as to minister to our personal comfort, æsthetic tastes, or luxury, are much too numerous to mention. The wool-combing industry of this country is a gigantic one, and gives employment to many thousands of people, and this is not to be wondered at when it is considered that our imports of wool amount to 795,091,310 lbs., of a total value of £33,001,622, and some of our principal cities have been built up in consequence of their textile industries depending on the supply of wool. Much literature has been produced on the subject of woollen textiles, and the machinery which has been called into existence since the invention of Cartwright's wool-comber in 1801.*

Apart from the wool itself, there are other products which are derived from it also. There is a yolk or oily secretion which spreads from the skin to the wool of the sheep, and which is described as a soap with a base of potash. Many uses have been found for this particular by-product, not the least of which is the use of the oily extract as an emollient. The yield of the potash varies from 70 to 90 lbs. of pure carbonate, together with 5 to 6 lbs. of sulphur and chloride of potassium, from every thousand pounds of raw wool. Another substance, called "cholesterin," is also obtained from the wool, but no use has so far been found for it.

Sheepskins.—Next in importance to the wool of the sheep is the sheepskin itself, which is used for a great variety of purposes. When the pelts are split, very thin leather is produced, which is prepared as imitation chamois, or is used for glove making, the leather itself being utilised for a great many different purposes, such as book-binding, furniture making, and so on.

Blood.—The utilisation of the blood of the sheep is somewhat similar to that of the blood derived from bullocks. This serum, however, is used in Ireland for the production of a particular kind of sausage called "Drosheen," which I have not found in any other country.

Mutton Hams and Sausages.—In many parts of Scotland especially it is common to treat the leg of the sheep in the same way as an ordinary pork ham and cure it, and this product is worthy of being much wider known, as are also the mutton sausages which find so much favour in the Midlands of England.

Fat.—The fat of the sheep is of a peculiar character. It is generally white in colour, and very much harder than beef fat, owing to the large percentage of stearine which is present. From this cause it has also a high melting-point —namely, varying from 31° to 52° C. Mutton

* "Journal of the Department of Agriculture of Victoria, Australia," Vol. V. part x.

* "The History of Wool and Wool-Combing," by James Burnley, 1889.

Hosted by Google

fat is very largely used for the covering of meat paste preparations, as it gives a hard cake on the surface. It is also used as an admixture in lard compound, as a substitute for the beef stearine which is generally present to the extent of about 20 per cent. in such preparations, and, owing to the fact that the fat itself is quite odourless, it is preferred above any other for these special purposes.

Violin Strings.—The intestines of small sheep are used for the manufacture of violin strings. They are simply spun like ordinary cord to different thicknesses according to the pitch required. The preparation of these violin strings involves considerable skill, and many establishments in this country and in foreign countries are devoted to this industry alone. Residual intestines, which may not be used for the finer violin strings, are generally spun into larger cords and used for the making of belts for transmitting the power in sewing-machines or even larger machines.

Milk.—Many of the races of sheep are used for milking purposes, and, notably in Holland, the sheep is extensively utilised for this purpose. At one time sheep-milking used to be very common in Scotland, ewe-milk cheese being prepared from the milk; but this custom has fallen into disuse. In France, however, the Larsac race of sheep is very extensively cultivated for its milk, from which the Roquefort cheese is prepared, and of which some ten million pounds' weight are exported from France annually. In the eastern parts of Europe, notably Servia, Bulgaria, and Hungary, the cultivation of sheep for their milk is quite a common practice, and great herds are collected together during the period of lactation, and the milk is mostly converted into cheeses of different kinds.

Sheep husbandry is, therefore, one of the principal pursuits of agriculture, inasmuch as the sheep provides so many of the comforts and necessities of civilisation. It is doubtful if any domesticated animal is more generally utilised throughout the world than the sheep, owing to the fact that it provides necessary food and clothing, with many luxuries as well. Although the bullock may figure in animal industry as producing the greatest number of products, it may be said that the sheep is capable of supplying all our wants in the shape of flesh, food, and clothing, but this could not be said of the bullock.

The utilisation of the residual by-products of the sheep in the United Kingdom is not studied at all from the scientific point of view, this being largely due to the fact that the quantities handled in any one place are not very large. It would seem reasonable, however, to suppose that, seeing that we have such large flocks and herds, it might be possible to aggregate the supplies of animals for slaughter in central slaughtering establishments, where the very best use could be made of all the residual products. As in the case of the bullock, this is entirely a question of education, and until a system of education is instituted from the point of view of the cultivation of animal industries, there is not much likelihood of any alteration in the present customs.

FOREIGN COMMERCIAL COURSES.

The International Society for the Promotion of Commercial Education has recently issued the full programme of lectures and other arrangements for the sixth meeting of the Society, which takes place this summer at Antwerp. Last year the meeting was held in London, at the School of Economics and Political Science, and some of the lectures were given in the meeting-room of this Society. Previous commercial courses were held at Lausanne (1907), Mannheim (1908), Havre (1909), and Vienna (1910).

The holiday course this year at Antwerp will be held from July 22nd to August 10th at the Institut Supérieur de Commerce, 41, rue des Peintres—probably the oldest, and certainly one of the best known, of the commercial colleges of Europe. The lectures, which will be given in French by leading professors and business men of Belgium, are grouped in three series:—

1. The economic development of Belgium.
2. The Belgian Congo.
3. Belgian art and monuments.

They will be given in the morning, commencing at 9 a.m., and also in the evening, thus leaving the afternoon free for the various excursions and visits to industrial undertakings which have already been arranged. The meeting is being supported by a large and influential committee of patronage, while the chairman of the executive committee, to whom the fee of 75 francs should be paid, is M. Ernest Dubois, Director of the Institut Supérieur de Commerce.

No country is better worthy of study from a commercial and industrial point of view than is thickly-populated Belgium, and young business men whose knowledge of the French language is sufficient to allow them to follow the lectures, would be well advised to make arrangements to attend the Antwerp meeting.

These courses of lectures provide an opportunity of acquiring a great deal of useful information about the business methods of our Continental trade rivals, and to a young man well started on a commercial career such an experience cannot be

Hosted by Google

other than helpful and suggestive. The lectures are really business talks by men who have been selected for their practical knowledge of the special branches of commerce with which they deal.

By no means the least useful object of the meeting is the opportunity it provides for rubbing shoulders with students of many nationalities; by means of a language common to all the student is able to compare the institutions of his own country with those of other countries of the world. It would be difficult to overestimate the advantages of such discussions, for they cannot but enlarge a man's outlook on life in general, and give him a breadth of view which could otherwise be acquired only by extensive travel.

It is, however, a matter for regret that very few Englishmen have, up to the present, attended the meetings arranged by the International Society. When one notes the avidity with which the young Swiss or German acquires, and stores up, information gathered at such lectures as these, one cannot help feeling that by not availing themselves of such opportunities of obtaining useful business knowledge our countrymen are losing a very great deal.

Mr. Cleveland-Stevens, the Secretary of the Commercial Course held last year in London, writes as follows in summing up the results of that meeting*:—"Here were two hundred foreign students—there were but half a dozen Englishmen among them—mostly teachers or pupils at the Continental commercial academies, institutes, etc., who willingly sacrificed their short vacation to go through this exceptionally strenuous course. Moreover, many of them do it year after year; those who have been to one of these meetings seldom fail to come regularly in subsequent years to the succeeding meetings. Without entering into any discussion upon systems of commercial education, one may ask whether such a movement as this should not commend itself to all students of business and industry. Can we not find young men in this country whom we may profitably send to the meeting and lectures at Antwerp next year?"

It is certainly a strange fact that in a great commercial country like this, the importance of a sound, practical knowledge of foreign languages seems never to have been properly appreciated. It is probably true that owing to the almost universal use of the English language, and to the fact that it is the medium of international intercourse in the East, the necessity for speaking other tongues is not brought home to the insular Briton to quite the same extent as it is to a Continental business man. There must, however, be some reason other than this for the indifference which has hitherto prevented any real, live interest being taken in the teaching and study of French and German in this country. This indifference is no doubt largely a heritage of the past caused by the fact that the requirements of the older universities formerly demanded of the great public schools an entirely classical curriculum, in which there was little room for modern languages. It is true that secondary day schools have, from the first, devoted much attention to the study of French and German, but these languages were, more often than not, taught by foreign professors who, on account of their faulty pronunciation of English and their lack of knowledge of the character of the English schoolboy, exercised little influence over their pupils, and were seldom able to maintain proper discipline.

This is now, to a great extent, a thing of the past; the universities are, at the present time, fully alive to the importance of a proper study of foreign languages and literatures, although it must be admitted that the number of open scholarships for modern languages is still very limited. The public schools, too, now usually select their modern language masters from Englishmen who have studied abroad, and in so doing are following a system which Germany adopted many years ago. There are still, however, not a few secondary schools, and even higher institutions, where the teaching of modern languages is hopelessly out of date. Very often the classes are too large to permit of efficient instruction, in other instances the pupils have very little opportunity of hearing or practising the foreign tongue because they are kept far too long to the dry routine of grammar, while the more advanced students are often unfairly handicapped by the presence in the same class of others who do not understand the spoken language.

The accumulated indifference to the value of a knowledge of foreign languages shown by all classes in this country for many years past has resulted in an apathy and a lack of enthusiasm which goes a long way to account for the sparse attendance of Englishmen at these foreign commercial courses. This indifference is noticeable at the ordinary holiday courses arranged each summer in various Continental countries.* These meetings are naturally attended by many English people of either sex, but these latter are, almost without exception, engaged in the teaching profession, and are practically obliged to spend part of their holidays abroad in order to maintain the standard of their French or German pronunciation. It goes without saying that some are keen students who regularly follow the lectures and make the most of their opportunities, but on the other hand there are many who have no heart in their work, and, in great contrast to students of other nationalities, look on the whole thing as a bore. It is certainly the rarest event to find an Englishman attending the course for the more or less disinterested motive of acquiring French or German merely for his own satisfaction, or for the sake of the culture which is derived from the study of a foreign language and literature.

That young English teachers are not eager to

* *Journal*, Vol. LIX. p. 930.

* "Table of Foreign Holiday Courses." Wyman & Sons. 2*d*.

Hosted by Google

avail themselves of a favourable opportunity for study abroad may be inferred from the fact that they do not take full advantage of the scheme, initiated by the Board of Education three years ago, for the exchange of teachers of modern languages between England, France, and Prussia. The number of English teachers placed in foreign schools as "assistants" in 1910-11 was fifty, but for the current year it has fallen to forty-two, of whom twenty-five are women. The last report of the Board of Education states that "the number of properly qualified male candidates for appointment in France is considerably below the number of available vacancies; and at the time of the preparation of this report (March, 1912), there were some ten posts in secondary schools in France for which the Office of Special Inquiries and Reports had been unable to find suitable candidates."

The teaching of foreign languages in this country has certainly improved during the past few years, and as some evidence of this improvement in London it is worthy of note that since the institution, ten years ago, of the viva voce examinations in foreign languages of the Royal Society of Arts, over 4,000 candidates have been awarded certificates. A fairly high standard is maintained, and the examination provides a good test of a candidate's ability to speak and write the language.

In London the County Council education authorities deserve much credit for the part they have taken in bringing about this improvement, and the teaching of foreign languages in their evening continuation schools is highly efficient. The Polytechnic in Regent Street has also, by means of an excellent series of lectures in French and German, done much to foster the study of these foreign literatures, but the lectures are, unfortunately, not attended by as large a public as their importance demands.

But, notwithstanding this more satisfactory state of things, one cannot but agree with the President of the Board of Education when he stated, only the other day in the House of Commons, that in the teaching of modern languages we are a long way behind our Continental competitors. One always expects a young German business man to have a good knowledge of English and French, and it is not easy to find one who has not; on the other hand when a German meets an Englishman speaking two or three languages he opens his eyes in astonishment, so exceptional is the circumstance.

Pupils in most secondary day schools devote a large proportion of their school hours to the study of French and German, and on leaving school at the ages of sixteen or seventeen have a fairly sound knowledge of the grammar, and can also read an easy book in those languages. A small proportion of these boys are able to consolidate their knowledge by a short residence abroad; the majority, however, being under no compulsion, and having no immediate incentive to continue their studies in this direction, rapidly lose whatever knowledge of the languages they may have acquired during many years of school life. French and German are not, of course, taught in schools entirely for the utilitarian purpose of enabling boys to speak these languages. The mental discipline and training of memory which the study of foreign languages encourages are also of great importance, and some authorities contend that their value from this point of view is as great as that of the classics. It does, however, seem very purposeless for a boy to spend so much of his school life in learning modern languages, a knowledge of which is bound, at some time or other, to be of practical use to him, only to give up his studies the day he leaves school. Surely some pressure should be brought to bear on these young men, either by parents or employers, to induce them to keep up their knowledge of modern languages. The time when a youth leaves school is just the moment when he has the best opportunities for continuing his studies in French and German; in fact he has, for the first time in his life, the chance of specialising. He has no longer the rather heavy burden of home-lessons which a somewhat crowded school curriculum demands, and in most cases he has the necessary leisure, more especially in the winter months, to attend some of the lectures and classes which are now brought to the doors of all.

The value of a short residence abroad for the purpose of learning a language is, of course, obvious. It may not be generally known that the Société d'Echange International des Enfants et des Jeunes Gens of Paris has built up an effective organisation for bringing into touch families in various countries who wish for a mutual exchange of their young people for the holidays, or for a longer period if necessary. It should prove an interesting experience to a schoolboy to spend his holidays occasionally in a foreign family, and a visit to France or Germany, paid at a fairly early period of school life, would undoubtedly quicken the interest he takes in these languages. To a youth preparing for an open competitive examination at the age of eighteen or nineteen, the spending of his school holidays abroad in order to practise the language, represents a valuable economy of time which should give him some advantage over his competitors.

It may, of course, be argued that English methods of commercial training are different from those of Continental countries, and it would be a mistake to condemn too readily our own methods. It is probably true, for instance, that our system, or want of system, provides a better opening for the man of initiative; it is, however, no use disguising the fact that the foreigner has come to look on our business methods as rather conservative, and it is partly for this reason that fewer young foreigners now enter London firms—except, perhaps, financial houses—as "volunteers" or unsalaried assistants than was the case ten or fifteen years ago.

During the last few years schools of commerce of almost university rank have been established in the big towns of the Continent, and it is the custom now for many young foreigners—the merchants of the future—to attend a course at one of these

Hosted by Google

institutions, afterwards coming to England for a few months merely to improve their pronunciation of the English language which they have studied to such advantage in the commercial high school. The more enterprising young foreigner who wants practical business experience goes very often to the United States rather than to England.

It is, of course, common knowledge that the commerce of Germany has increased by leaps and bounds during the past few years. Anyone to-day revisiting one of the great commercial centres of that country after a lapse of, say, ten or a dozen years, cannot fail to be struck not only by the increased size of the town, with its new and magnificent public buildings and business premises, but still more by the well-dressed appearance and air of prosperity presented by its inhabitants of the middle-class, a prosperity which is largely consequent upon the improved financial position of officials and employees of commercial houses and industrial concerns.

Just how much a superior system of commercial and technical education has had to do with this success it would not be easy to say; that the young German devotes more time than his British *confrère* to preparing himself seriously for a commercial career there can be no doubt, and it would be hard to deny that this has done much to bring about German commercial success and has been the means of diverting much trade into German channels. In this connection it is not unworthy of notice that in the commercial world of London young merchants of foreign extraction, men perhaps whose fathers have become naturalised Englishmen, are usually successful in trade largely because their knowledge of foreign languages has enabled them to get a better insight into the details of their business.

In the strenuous commercial rivalry of to-day, and still more of the future, success will come only to those who have exhausted every means of studying the different phases of the special branch of commerce in which they are working. The most profitable sources of study must surely be the business methods and procedure of foreign competing firms, and the man who is able to devote his vacation during three or four consecutive years to attending the courses arranged in various countries by the International Society would lay in a store of knowledge which would prove to be of inestimable value to him in the future.

C. D. C.

THE WORLD'S PRODUCTION OF MANGANESE.

Manganese is obtained commercially from manganese ores, manganiferous iron and silver ores, and manganiferous residuum from zinc roasting. Manganese ores are found in many parts of the United States, but only at a few places do they occur in sufficient quantity to be of high commercial value. They have been mined in the New England, Appalachian and Piedmont regions in the eastern United States, in northern Arkansas, and to a small extent in central western California. Large quantities of manganese ore have been mined in New Brunswick and Nova Scotia, and small amounts in Quebec and Ontario. In Newfoundland, manganese carbonate of brownish colour occurs. There are manganese deposits of importance in the Province of Santiago de Cuba. A bed of manganese ore of superior quality is reported from the island of St. Martin in the West Indies, and another deposit has recently been discovered in Hayti. Manganese ore has not been mined to any extent in Mexico. The ores are widely distributed in Brazil; large deposits occur in the State of Minas Geraes, and smaller ones in the State of Bahia. Ores are also reported from the States of Matto Grosso, Parana, and Santa Catharina, and from the region of the Amazon River. In Chile the manganese deposits are all on the west slope of the Andes Mountains in the Provinces of Santiago, Coquembo and Atacana. As regards Europe, manganese occurs in Spain, in the Provinces of Huelva, Oviedo, Teruel, Ciudad Real and Murcia. There are eight or ten mines in the Province of Alemtejo, Portugal. The principal manganese mines of France are in the Departments of Saône-et-Loire and Ariège. Smaller deposits occur in the Departments of Indre, Aude, Hautes-Pyrénées and Lozère. Belgium does not produce manganese ores proper, but a considerable amount of manganiferous iron ores. The centre of production for these is the Province of Liège. They are also found elsewhere in Belgium. The chief occurrence of manganese in Germany is along the Rhine in the districts of Wiesbaden and Coblenz. Smaller deposits are found in the Harz Mountains, in the Bonn district and in Coburg Gotha. Manganese ores of three types occur in Sweden. Manganese ore is found in different parts of Austria-Hungary. In Italy the chief manganese deposits are on Monte Argentario at Carrara, at Rapolano, and on the island of Elba, at Turin, Pralorgnan and at Gambatesa. There are also small mines at Iglesias, on San Pietro Island, off the west coast of Sardinia. Manganiferous iron ore occurs in Tuscany, while in Greece it is found at Laurium. In both European and Asiatic Turkey, manganese ores are found, in the former in southern Macedonia. In the latter they are reported from Aptal in Trebizond, in northern Asia Minor near the Black Sea, and also from Flatza, in the same region. On the island of Cyprus, manganese ores occur at Strullos, near Larnaka. Russia has been for many years the leading producer of manganese in the world, the principal centres of production being in the Province of Kutais. Large deposits of manganese ore occur in Tunis, near Ain-Mulares. The quantity available is said to reach 1,000,000 tons. An important discovery of manganese has recently been made at Caledon, Cape Colony. The deposit is said to contain 30,000 tons of ore, with a manganese content of 42 per cent. Manganese ore

Hosted by Google

is found in Madras and Bombay, in Bengal and in Lower Burma. Small deposits of manganese ore, containing 1·6 per cent. of cobalt, occur at Ampituja, Ceylon. Moderate quantities of manganese oxide are mined in Japan. Maganese deposits are found in the Philippine Islands, in Java, and in British North Borneo. Manganese ores are found in New Zealand, and in Australia, particularly in New South Wales, South Australia and Queensland. In the United Kingdom, the bulk of the manganese ore worked at present is in North Wales in the form of a bed of ferruginous manganese intercalated among the Ordovician (lower silurian) shales, near Aberdaron, in Carnarvonshire. Other beds are found in Merionethshire and in Ireland, in the district of Cork.

ARTS AND CRAFTS.

The South African War Memorial.—Writing and illumination have taken their place of late amongst the crafts that are largely taught and quite extensively practised. Indeed, hand-written and illuminated booklets are a feature of nearly all the Arts and Crafts exhibitions up and down the country. But, for all that, the illuminated record of the names of those who died in the South African War, which is to be preserved in Cape Town Cathedral, and was shown for awhile at the Victoria and Albert Museum, South Kensington, has probably come as somewhat of a revelation to a good many people. The public has become accustomed, it is true, to short poems, chapters from the Bible, the Communion Office, and other writings of inconsiderable length, carefully written and elaborately ornamented, but a folio volume of some 440 pages, written entirely by hand, and decorated on nearly every page with illuminated designs, is an undertaking which few would have expected to see carried through in the hurry and bustle of the twentieth century. That it has been successfully accomplished is matter for congratulation to all concerned in its production.

The planning, writing, and gilding of the book were entrusted to Mr. Graily Hewitt, and he has given us a volume which more than upholds his own reputation, and, by its character, freshness, and general excellence, justifies the claims of the pen to produce work with which the printing-press cannot in any real sense compete. Some hand-written pages make one sigh for a good piece of printing: the South African War Memorial proves beyond dispute that, in the hands of a really first-class scribe, penwork is a thing of beauty which, by virtue of its power of adapting itself to fill a given space, and the almost infinite variety which it exhibits, is peculiarly fitted to be used for a document of lasting and historic interest. Mr. Graily Hewitt has employed a version of a good Italian formal script of the fifteenth century for the body of the work, and has executed his headings in Roman capitals. It is, of course, in these last that he has had an opportunity, of which he has availed himself to the full, of showing how truly decorative good lettering in itself can be.

Mr. Allan F. Vigers's illuminations, whether comparatively simple or more elaborate, show throughout very competent workmanship. The titlepage and the heading of the index are wonderfully rich and intricate pieces of work, somewhat Oriental in feeling, but not quite like anything else ancient or modern, and very delicately treated; but there is a certain heaviness about the ornamentations of the majority of the pages which keeps them from being altogether satisfactory. It is not quite a pleasant surprise to find that heraldic badges and devices, which would have helped considerably to give interest and life to the decorations, have been altogether dispensed with. Mr. Vigers's scrollwork is vigorous and well-considered, and the plan of introducing into it flowers and animals, typifying the various regiments, is certainly to be commended, but these little additions are necessarily less striking than good heraldic ornament would have been. However, since the keynote of the decorations is peace, the book, perhaps, gains in consistency what it loses in interest by the omission of military symbolism.

The Silk Exhibition.—The Exhibition of British Silks held at Knightsbridge certainly merited all the attention it has received, for it showed that British manufacturers can and do produce brocades, damasks, and other silks of a quality and a beauty which public opinion in this country is inclined to imagine can only come from France. Perhaps the first thing which struck one at the exhibition was the beauty of the colour which greeted the visitor on every side. It is, of course, comparatively easy to get good colour with a surface so glossy as that of fine silk, but for all that, the colours to be seen at Prince's Skating Rink were, as a whole, wonderfully fine. They showed, moreover, to far better advantage than they might have done, because so many of the exhibitors had arranged their stands in tones of one or two colours, or had taken special pains and shown real taste in putting side by side shades which helped each other instead of clashing. One stand, which was rather forcibly attractive, was decorated entirely in blue and purple, while another was, as it were, papered with a shot silk, which took a different hue in the various lights which fell upon it.

When we turn to the design of the fabrics, the state of affairs seems to leave some room for improvement. There were good patterns in abundance, but for the most part they were copies or fairly close renderings of old French and Italian velvets and silks, or of the later English materials of the period of Dutch William and his successors. The modern designs as a whole were not very inspiring. One firm of manufacturers seemed so conscious of this fact that they had hung their damasks (probably from motives of economy, to save cutting), in such a way that, while in one width the pattern was the right way up, in the

Hosted by Google

second it was standing on its head. It seems as though some of the leading British silk manufacturers have made up their minds that, as regards at least velvets, damasks, and furnishing silks in general, success is hardly to be attained through producing anything distinctively British, certainly not by offering the public anything new in the way of design. They apparently either do not want, or cannot get, modern designs for this class of material. Anyway, they go on reproducing good old patterns. There is something to be said for this procedure, of course; it is eminently safe, and within certain limits has excellent results, but it can hardly be called enterprising. William Morris was, undoubtedly, a head and shoulders above the ordinary trade designer, but Messrs. Morris & Co.'s stand at Knightsbridge bore witness to the fact that the best English design of his period, at any rate, could not only compete successfully with the old on its own ground, but has the added interest of a freshness and life which seldom survive in a pattern which has been copied and adapted over and over again, and has grown stereotyped by much use. Messrs. Warner & Sons, of Newgate Street, were, as was to be expected, by far the most important exhibitors, and their fabrics were to be seen not only on their own stands but (without mention of the makers' name) on those of the leading retail firms. Their exhibit covered a very wide field, including damasks, brocades, lampas, brocatelles, velvets and tissues wrought in gold and silver threads, as well as printed silks and thin materials for dresses, and was remarkable for its technical excellence. Some of the tissues into which metal was introduced were fine bits of workmanship as well as gorgeous pieces of colour, and the show as a whole would have more than held its own had it been compared with the striking exhibits of the French manufacturers which have been so important a feature of some of the more recent international exhibitions held on the Continent.

The stand of the Gainsborough Silk Weaving Company of Sudbury, Suffolk, was the most interesting of the smaller exhibits. The Genoa velvet in blue and brown on a neutral-coloured ground with skilful use of cut pile and terry; the mole-coloured velvet figure on a background of brocade, forming as it were a pattern on a pattern; the brocatelle with a ground made interesting by being tied down irregularly, and the clever copy in brocading of the effect of old embroidery were all worth looking at. Messrs. Burnet & Co., of Garrick Street, made a special feature of materials suitable for ecclesiastical purposes, and indicated that a much better effect can sometimes be obtained, when funds are limited, by the employment of a good woven fabric instead of poor embroidery. Their woven altar frontal, with its kneeling angels and central vine, would look far better in many a church than a piece of second or third-rate needlework.

Messrs. Pearsall and Co. showed a fine collection, or perhaps it would be better to say selection, of their well-known embroidery silks, and the flosses exhibited by the British Standard Dye Works, of Birkenhead, covered a range of colours for which workers sometimes seek in vain.

The Women's Guild of Arts and Crafts.—A certain number of the exhibitions devoted exclusively to women's work are not of such a character as to prove woman's superiority over, or even her equality with man in the field of Arts and Crafts. The little show held by the Women's Guild of Arts and Crafts at Lindsey Hall, Notting Hill Gate, however, if it could not be called very remarkable, did at least demonstrate what really capable, competent, and workmanlike work women are doing in the various branches of applied art. The guild includes many of the better-known women craft-workers as well as painters and sculptors, and they exhibited for the most part of their best. Amongst the most interesting pieces of needlework were two pieces by Mrs. Morris, of which the portière embroidered from her husband's design was a very striking piece of work. Miss May Morris exhibited a very dainty piece of boldly-executed embroidery on muslin, worked in exquisitely delicate colours, and Mrs. A. H. Christie's four d'oyleys were dainty and instructive pieces of workmanship, though her canvas-stitch embroidery serving as a kind of frame to a mirror, though beautifully executed, was far from pleasing both in colour and design. Mrs. Dawson's silver cup and cover with enamel decorations of gorgeously coloured nasturtiums on a deep blue ground showed how beautiful well-manipulated enamel colour can be, and Mrs. Gaskin's jewellery daintily shown on a background of mousy brown velveteen, was well designed and characterised by a sense of style. Miss Katharine Adams's bookcovers were noteworthy, as usual, on account of their tastefulness and restraint. Mrs. Stabler's little figures are always full of feeling, but they hardly seem to gain by being carried out in glazed earthenware. That may be due, however, to the quality of the material in which they are reproduced. They might quite possibly prove themselves admirably adapted to execution in pottery, if they were rendered in fine porcelain. Mrs. Bernard Jenkin's memorial panel of Florence Nightingale executed in a kind of mosaic of opaque glass paste is admirably adapted for its purpose. In short, the little exhibition more than justified itself by the high standard which was maintained by many of the exhibitors in the various crafts represented.

GENERAL NOTES.

Memorial Tablets.—A memorial tablet has been affixed by the London County Council to No. 32, Craven Street, Strand, the house in which Heinrich Heine lodged for about three months when he visited England in 1827. He was much impressed with London, describing it as "the

most remarkable phenomenon that the world has to show to the amazed mind of man." A tablet has also been placed on Devonshire Lodge, No. 28, Finchley Road, N.W., the home of Thomas Hood for the last two years of his life. This is the second tablet commemorating a residence of Hood's, another having been fixed by the Council in 1907 to No. 17, Elm Tree Road, N.W., the house in which the famous "Song of the Shirt" was written.

TELEPHONE SERVICE IN PRINCIPAL EUROPEAN CITIES.—*L'Illustration*, of Paris, gives the following statistics, showing the number of telephones in seventeen of the principal cities in Europe in 1911, and the ratio of inhabitants to each. From this it will be seen that whilst Stockholm possesses one instrument to every 4·7 inhabitants, neither London nor Paris are so well served, the ratio being 1 to 26·3 and 36·7 inhabitants respectively.

	Number of Instruments.	Number of Persons to each Instrument.
Stockholm	72,000	4·7
Copenhagen	45,000	11·4
Christiana	16,000	14·2
Stuttgart	16,000	15·5
Berlin	122,500	16·6
Berne	4,300	18·3
Munich	27,000	22·1
London	172,000	26·3
The Hague	8,000	36·1
Paris	75,400	36·7
Brussels	16,900	37·9
Budapest	18,600	39·4
Vienna	47,000	44·4
St. Petersburg	30,600	55·0
Rome	9,500	60·5
Lisbon	3,000	115·0
Madrid	3,500	155·0

THE UNITED STATES CEMENT PRODUCTION.—In 1910, according to a report recently issued by the United States Geological Survey, the production of Portland cement in that country amounted to 76,549,951 barrels, with a value of £14,376,000. This shows an increase over the 1909 output of 11,558,520 barrels, or nearly 18 per cent., and an advance in value of £3,200,000, or more than 29 per cent. This increase alone is greater than the total output of Portland cement in 1900. In addition to Portland cement there were also produced 1,139,239 barrels of natural cement, and 95,951 barrels of pozzuolanic cement, a total of 77,785,141 barrels.

CATTLE TRADE BETWEEN ARGENTINA AND ITALY. —A new and important trade in live cattle and frozen meat has been established of late between Argentina and Italy. During 1911, upwards of 34,000 head of cattle were landed at the port of Genoa, of which about one third were sent by rail to Switzerland. The remainder were forwarded chiefly to Rome and Milan. The quality of the meat was, generally speaking, satisfactory, although in some cases perhaps a little too fat to suit the Italian taste. About 10,000 tons of frozen meat was also landed at this port last year, but, in spite of its low price, public opinion is somewhat prejudiced against it.

INDUSTRIAL EDUCATION FOR NATIVES IN ERITREA.—The results obtained at the first examination ever held of the pupils of the industrial school at Chezen (Eritrea) are very encouraging. Established in 1909, on a very modest basis, by the (Italian) colonial government, this school has been attended, on the average, by seventy-five pupils (all Mussulman) whose parents appear fully to appreciate the advantage of a sound education for their children. The instruction is entirely gratuitous, and even as many as thirty pupils are boarded and clothed besides, free of charge. All the pupils are taught the Italian and Arab languages (spoken and written), the four rules of arithmetic, the Koran, as well as some elementary general knowledge. In addition to these subjects, pupils can learn telegraphy (the Morse system), typewriting, as well as the trades of the carpenter or blacksmith. It is hoped shortly to add the art of printing in Arabic characters.

NEW ZEALAND WINE PRODUCTION.—About one thousand acres in New Zealand are now under grape culture for wine. New Zealand grapes, which grow chiefly in the northern part of the North Island, produce good wine of the claret and Moselle type. An acre of grapes in the northern part of New Zealand can easily be made to yield five hundred to seven hundred gallons of wine annually. New Zealand cannot compete with hotter countries in producing full-bodied wine of high alcoholic percentage, and the local grapes do not have sufficient saccharine matter for ports, Burgundies, or sherries, without artificial assistance; but for light, popular wines, such as clarets and Moselles, climate and soil seem well suited. About seven years ago the New Zealand Agricultural Department established a viticultural experiment station in the North Island to demonstrate to intending vine-growers the most suitable varieties of American stocks on which to graft the best grapes, with information on the art of wine-making.

EXPERIMENTAL CULTIVATION IN LYBIA.—A proposal for establishing experimental gardens in various parts of Tripoli and Cyrenaica, now under Italian rule, is under consideration by the Ministers of War and of Agriculture. The *Bolletino dell Società Italiana di Agricoltura* states that the gardens, which would be cultivated by the garrison under the guidance of competent instructors, might render valuable assistance in testing the fertility of the soil and the suitability of each locality for growing different crops. The general direction would be entrusted to a professor well acquainted with tropical flora and cultivation.

CANTOR LECTURES.

THE MEAT INDUSTRY.

By LOUDON M. DOUGLAS, F.R.S.E.,
Technical Adviser on Animal Industries.

Lecture III.—Delivered February 19th, 1912.

THE PIG AND ITS PRODUCTS.

Swine husbandry has long formed a leading feature in the economy of the farm, and from ancient times until the present day the pig has been cultivated very largely, because it is easily housed and fed—it acts, as it were, as a scavenger on the farm. For the same reason the rural householder often maintains one or more pigs, so as to utilise the food residues from the household.

This feature especially prevails in Ireland and in the northern part of England, but, otherwise, the pig is mostly associated with agriculture.

HISTORICAL.

Many ancient authors have dealt with the pig, and the student of early agricultural literature cannot fail to notice that in the schemes of agriculture as laid down by such authors as Thomas Tusser in the sixteenth century, Fitzherbert and Gervaise Markham in the seventeenth century, Edward Lisle at the beginning of the eighteenth century, John Mills in 1776, and Arthur Young at the beginning of the nineteenth century, it is recognised that British farming would not be complete without the cultivation of Swine Husbandry. At so early a date as 1705 we find Edward Lisle, who was a noted writer in his day, describing in his " Observations in Husbandry " how pigs were then fed in Wiltshire, and the business became so notable that from that day until now " Wiltshire Bacon " has been the description applied to meats that are dressed and cured in a certain way throughout the world. It is to Scotland, however, that we are indebted for the first treatise on the pig, from the point of view of the curing of bacon. A Scottish farmer, called Robert Henderson, wrote " A Treatise on the Breeding of Swine and the Curing of Bacon " in the year 1811, and he may be said to have placed the business of curing, for the first time, upon a methodical basis.

The Breeds of Swine.

There are many different breeds of swine, every country having its own particular type. Generally speaking, the modern types of all countries take their origin from the British breeds, and this remark applies all over the world wherever swine are cultivated. There are, however, certain breeds which stand out pre-eminently above all the others in the United Kingdom at the present day, and these are six in number, namely:—

The Large White Yorkshire.
The Middle White Yorkshire.
The Large Black Sussex.
The Tamworth.
The Berkshire.
The Lincolnshire Curly Coated Pig.

In different countries there are other breeds, but they are not in sufficient numbers nor have they sufficiently pronounced characteristics to warrant any special classification, and there would seem to be a tendency to confine the British breeds to the six mentioned. In some countries where bacon-curing for the British markets has developed quickly, the British types of pigs have been crossed with the native breeds, and independent types have in this way been produced; but their leading characteristics and points of excellence are practically the same as in the British breeds.

Statistics.

In many countries the rise in the numbers of pigs has been very great, the tendency all over the world being towards rapid increase, which would seem to signify that there is a continuous and increasing demand for pig products. The number of pigs throughout the world may be stated at 142,272,275, which is the estimated figure inclusive of Europe, North and South America, Asia, Australia and Africa.* Out of the total number by far the largest figure belongs to the United States, there being in that country 59,288,592; † next in importance comes Germany with some 22 millions of pigs, the balance of the total being made up of smaller numbers, the United Kingdom contributing only a little over 4 millions, made up as follows:—

Pig Supply in the United Kingdom.

Great Britain, 1911	2,822,154
Ireland, 1910	1,200,005
	4,022,159

* "Statistique des Superficies Cultivées, de la Production Végétale et du Bétail," Institut International d'Agriculture, Rome, 1910.

† *Cincinnati Price Current*, January 4th, 1912.

This is rather strange, seeing that the British people are such lovers of pig products, and it has often been subject of comment that British farmers do not appear to appreciate the fact that there is a constant and ever-increasing demand for pig products in the United Kingdom.

The imports alone of bacon and the principal pig products are of a gigantic nature, and represent a value of nearly 20 million pounds sterling per annum.

In addition to these imports there are other pig products which represent vast sums of money, such, for example, as lard, which is imported to the value of £4,251,758,* and minor products, such as pigs' bristles, gelatine and margarine, a large proportion of which consists of lard derived from pigs. Besides these again, there are food preparations brought into this country in the tinned state and in glass moulds which are of immense value, but which cannot well be separated out from other preserved provisions. Sufficient, however, has been said to illustrate this particular point, namely, that a vast sum of money is being paid to other countries annually for pig products, a large portion of which at least could very well be retained in this country.

Swine Husbandry.

It must be understood that the breeds of swine which have been mentioned are not looked upon as being desirable in themselves for making the best pig products. The cross-bred pig is generally preferred, and is looked upon as being more profitable than the pure-bred animal, more especially for bacon-curing purposes, where the kind of pig that is wanted is one with a small proportion of bone to flesh, the live animal being of a somewhat rectangular shape and the fat of the carcass being firm to the touch, when at the normal temperature of the atmosphere. The head should be neat in shape, with a light neck and shoulder, and the side of the animal should be long, with a moderate depth. These features are so well understood amongst breeders that there is no difficulty in producing them from generation to generation, the scientific breeder knowing very well that this particular conformation will return the best price. It is also known that an animal weighing twelve stone dead weight, that is to say, with the primary offal removed, and being equal to about 15½ to 16 stones live weight, should arrive at maturity in from seven to eight months. It is within these few principles that successful pig-breeding lies.

The feeding of the pig is the first consideration, and a balanced ration to suit local conditions is what every pig-breeder should try to arrive at. The food in different localities will necessarily vary, and in arriving at the ration it will be necessary to take into consideration what is the food value of the material available. As a comparative basis it may be said that an average well-balanced food will consist of: 1 gallon separated milk, 3 lbs. potatoes, and 4 lbs. barley meal per pig per day, the ration being divided up into three portions and given at regular intervals during the day. Such a ration will be equivalent, in fattening a pig of over 80 lbs. weight to begin with, to a gain of something like 15 lbs. weight per week. The whole question of breeding and feeding, however, is a very extensive one, and would warrant very much closer and more elaborate consideration than we can possibly give it here, where we can only indicate the general principles which must be recognised so as to command success.

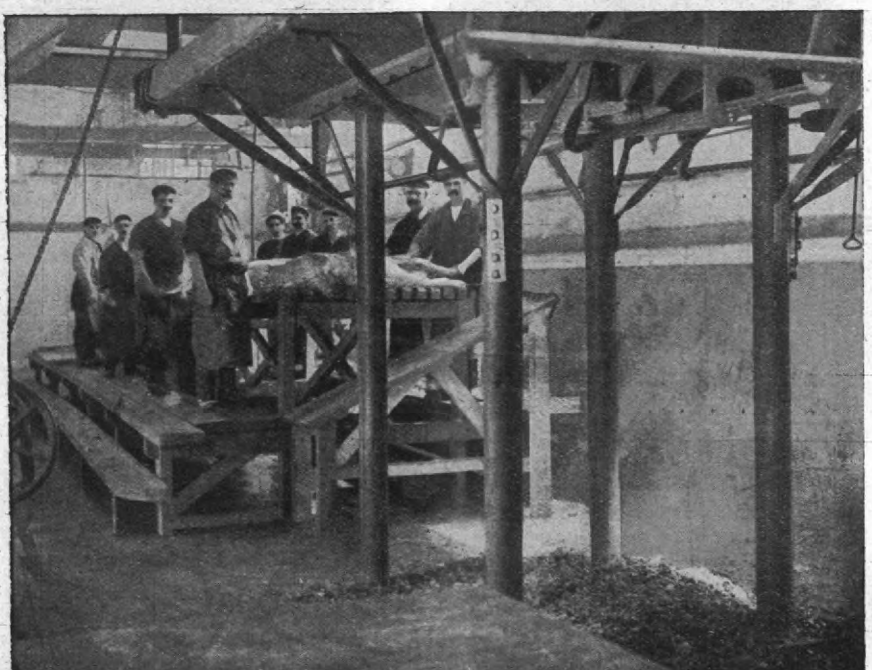

FIG. 11.—VIEW SHOWING SCUTTLING TABLE AND BASE OF SINGEING FURNACE.

THE HANDLING OF THE PIG.

So far, there has only been one attempt to arrive at the number of factories and the people employed in connection with bacon-curing and kindred industries in the United Kingdom, and these figures are very interesting.* They show that in bacon-curing factories in the United Kingdom we produce 1,716,000 cwts. of bacon and 457,000 cwts. of hams every year, and this reckons out to a total value of £7,023,000; but there are other products, such as salted pork, lard, sausages, pigs' heads, sausage casings made from intestines, preserved meats, such as brawn, tinned meats, etc., offals and residual products, all of which contribute to make up the total to £10,509,000 as the value of these products in the United Kingdom, and it would appear that 7,294 persons are employed in this particular industry. But these figures do not take account of the pork purveyors throughout the country, who number something like 10,000, and who must handle amongst them at least an equal quantity of pigs, which are converted into fresh pork and smaller products in their shops. It will be seen, therefore, that the industry of Swine Husbandry and the manufacture of pig products is a comparatively small one in the United Kingdom. The general deduction to be made from the figures given is, that the business is neglected in this country and that advantage is taken of our indifference in the matter by many foreign nations, who send their pig products to our markets.

condition, and it is the custom to pay for the animal by live weight. In some districts pig breeders prefer to be paid by the dead weight, viz., the weight of the carcass, minus the primary offal, consisting of the hair, blood and viscera. The dead weight is represented by the carcass in this condition, but if the weighing takes place while the flesh is warm there is always a deduction made varying from 2 to 4 lbs. per carcass, according to local custom, as a set-off in case of loss incurred by the evaporation which takes place during the dissipation of animal heat. In British factories the live pig after being weighed is merely passed on to sties, where it is allowed to rest over a night if possible, so that all traces of excitement may have disappeared.

Bristles.—It is at this point that in Russia, Hungary, France, and one or two other countries, the bristles from the back of the pig are cut off by means of strong scissors, the bristles being collected by hand, and only those are taken which surmount the ridge of the back, as in that particular place they are strong. It will be obvious that these bristles can only be gathered where the breed of pigs possesses strong hair. The hair of British breeds being of a soft or silky character does not lend itself to this business at all. Those breeds of pigs, however, which have been derived from the wild boar exhibit this feature very strongly, and it is from them that the supplies of bristles are taken. It is a very substantial industry, as may be gathered from the fact that we imported last year (1911) 4,727,063 lbs., at a value of £709,180, the average price reckoning out at about 3*s.* 6*d.* per lb. These bristles are used for tooth-brush making, and have first of all to be selected and bleached. The business gives employment, in certain centres where it is specialised, to a large number of hands, as most of the work cannot be done except by hand labour.

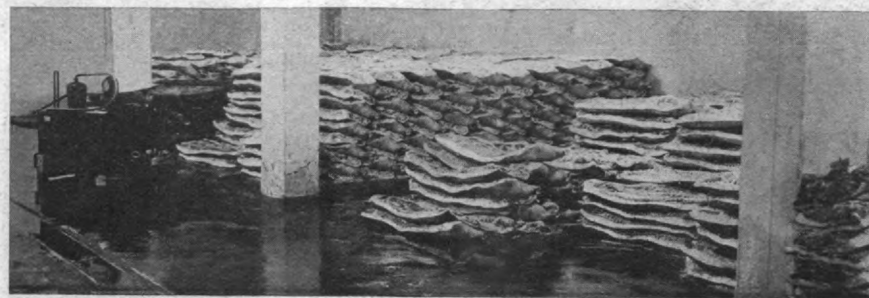

FIG. 14.—CURING CELLAR IN AN IRISH BACON FACTORY.

BACON CURING.

The principal use for the pig is the manufacture of bacon and hams, and the process of conversion into these commodities has now been reduced to a thoroughly scientific basis. At one time, not so long ago, the curing of bacon was looked upon as being a secret business, and the recipes were supposed to be handed on from one generation to another, but never written down. Happily, all that mystery has disappeared, and it is possible now to learn the whole of the process accurately from text-books which are available

on the subject.* A brief sketch of the process, however, will be of interest at this particular point.

The pigs are driven in to a catching-pen and are caught up, one by one, by a chain with a ring at the end of it, which is used to form a noose. The chain is slipped over one of the hind feet and the animal is hoisted head downwards to an overhead bar, and is there instantly slaughtered by the cutting of the main blood-vessels of the throat. I am inclined to think that although this is the universal practice, it would be more humane if the animals were first of all rendered unconscious, which could easily be accomplished by using a round-headed mallet. A sharp stroke from this weapon upon the front of the skull would produce temporary concussion and unconsciousness, and would in no wise interfere with the value of the carcass afterwards.

When the animals have been bled, the carcasses are pushed along on to a dumping table, where the shackling chains are removed, and they are then thrust into a tank containing water at a temperature of from 160° to 185° F., where they are scalded and the hair removed. After this they are passed on to a singeing furnace, which

is used to singe the carcasses where Wiltshire bacon is produced. This particular feature, namely, the singeing of the carcasses, produces a certain flavour in the meat and also serves to remove the remainder of the hairs which may be left. The subcutaneous fat, which might otherwise be soft in the cured material, is melted, and when the singed carcass is withdrawn after twenty-five seconds from the singeing furnace this fat immediately cools again and becomes hard. The singed carcasses are cooled as they emerge from the furnace in a bath of cold water, and are hung upon the dressing bars, where they are cleansed and disembowelled. Singed or unsinged carcasses from this point are treated in exactly the same way. They are first of all cleansed with cold water and scraped clean, the intestinal offal is removed and carried away to a department where it is handled by itself. The carcass, with the kidney fat remaining, is allowed to hang on the bar for some time in the dressed state, and it is at this point that it represents what is known as the "dead weight." The carcass is then split, the back-bone or vertebral column being removed; the secondary offal, consisting of the head, feet, and kidney fat, is all removed. The removal of the vertebral column liberates the two sides, which are allowed to hang until their temperature is somewhat adjacent to the atmospheric temperature, after which they are put in a chill room and cooled to about 38° F., by means of a current of cold dry air, which is set in circulation by a fan over pipes forming part of the circuit of a refrigerating machine. When these sides are reduced to 38° F. they are ready for curing, and are then transferred to the bacon-curing cellar, where the blade-bone is drawn out. The curing is then proceeded with, and it consists of pumping each side at a pressure of 40 lbs. to the square inch, with a pickle of recognised composition. The pumping is conducted by means of a pickle pump, to which a needle is attached, and this needle has a number of perforations arranged in a spiral manner through which the pickle is discharged, and in this way at once comes in contact with the tissues of the meat. When this has been done, the sides are laid one by one on the floor of the curing cellar, which is maintained at a temperature of 42° F., and the atmosphere must be humid and moist. The sides are covered over with an equal mixture of saltpetre and curing preservative, on the top of which is placed a heavy layer of salt. Under these conditions the curing proceeds, and the salt, as it melts, takes the place of the meat juices. At the end of about fourteen days the process is complete. The bacon may then be sold as mild-cured bacon, or it may be washed, dried and smoked, and sold as smoked bacon. It will not, however, keep very long in this mild-cured condition. Should it be necessary to keep the bacon for a long time, then it will have to remain in the salt for a proportionate period. Farm-cured bacon, as a rule, is kept in salt for

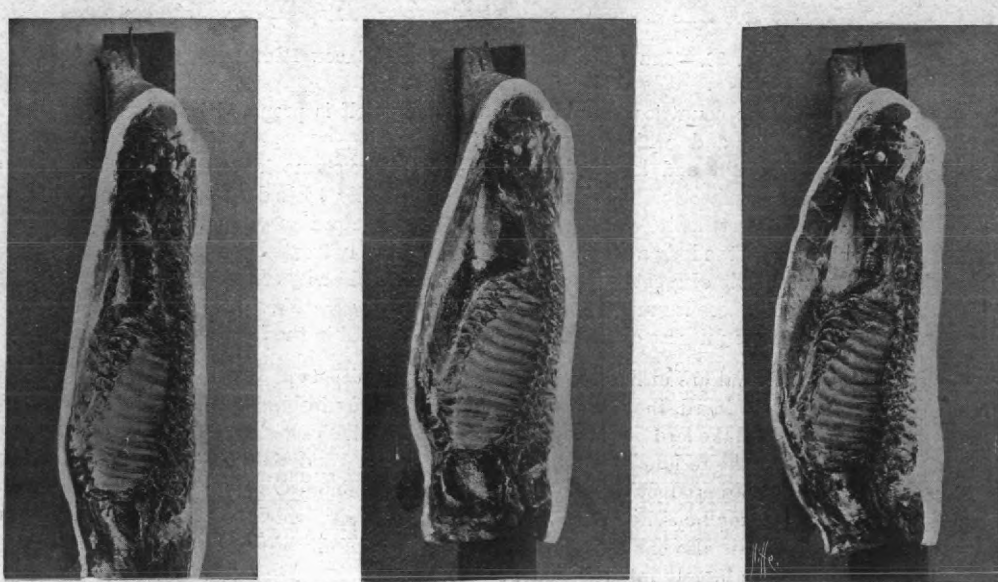
at least twenty-eight days, and generally is intended to be kept for many months afterwards.

The Curing Process.—The exact process which goes on in the production of bacon is not merely the displacement of the meat juices by a solution of salt and curing material. There is also a certain decomposition proceeding, due to the presence of micro-organisms which are always to be found where flesh of any kind exists. These putrefactive organisms assist in the curing process by breaking down some of the tissues of the meat, notwithstanding the presence of salt, which has no antiseptic effect on some of them. This is how the bacon flavour arises as distinguished from fresh or pickled pork. The flavour is largely due to decomposition.

Other Products.—Bacon and hams are cured in pretty much the same way, and there are many different forms in which these commodities are presented to the public eye, peculiar cuts and sections being popular in different neighbourhoods. These are mere details, however, and are not affected by the methods of curing which are practically identical throughout. There are, necessarily, the heads, feet and houghs to be dealt with, and these are generally immersed in pickle of a recognised density, and are cured to suit the public taste.



1. Lean Sizable. 2. Medium. 3. Fat.

FIG. 22.—TYPICAL SIDES OF DANISH BACON.

Blood.—One of the large by-products in a bacon factory is blood-puddings, which are simply composed of pigs' blood, some barley or groats, pieces of fat and flavouring herbs and spices. In some districts small factories exist where tons of these commodities are produced every week.

Pork Sausages.—Pork sausages are by far the most popular of the products in connection with bacon, and there are many factories which exist for the purpose of producing these as their main product. It has been computed that there are 5,000 tons of pork sausages produced in the United Kingdom every year.

Other Sausages.—Not only are there pork sausages, but there are a great many other kinds produced in the modern bacon factory, as there are also such commodities as galantines, brawns, pork pies and many other specialities. These may be included under the heading of *charcuterie*, which is a branch of industry that is very largely practised in some countries, notably in France and Germany, and which involves considerable technical skill and knowledge of cuisine. This is not the place to enter into the details of this wide subject, as it would lead us too far and would occupy too long a time.

Lard.—Lard is an article of great importance to the bacon-curer, and there is much expensive machinery devised for the purpose of converting rough lard into a marketable product. The different fats in the animal are utilised so as to produce different grades of lard, the best quality being obtained from the flake lard or kidney fat, rough grease, including the residual fats of the carcass, being the ultimate product.

Besides being of use for household and confectionery purposes, lard is also one of the bases of margarine, and enters largely into its composition. As we have seen, there is a great demand for lard in the United Kingdom, which is not satisfied by the home product. In 1911 we imported from the United States of America 1,719,292 cwts.; from other countries, 103,468 cwts., the total value being £4,251,758.*

It will thus be seen that we are compelled in this country, not only to import an immense quantity of bacon and hams, but we are also compelled to go overseas for a large portion of the fat required for domestic and confectionery purposes.

Other Pig Products.—A good deal of capital is represented in the utilisation of the intestinal offal of the pig. The casings or intestines are largely in demand for various kinds of sausage making. The bladder is utilised for the packing of lard. The stomach is the principal source of pepsin, which is used so largely in its various forms for the conversion of the proteids into soluble peptones. The process of elimination of the pepsin is a highly technical one, and the product itself is prepared in a great variety of forms.

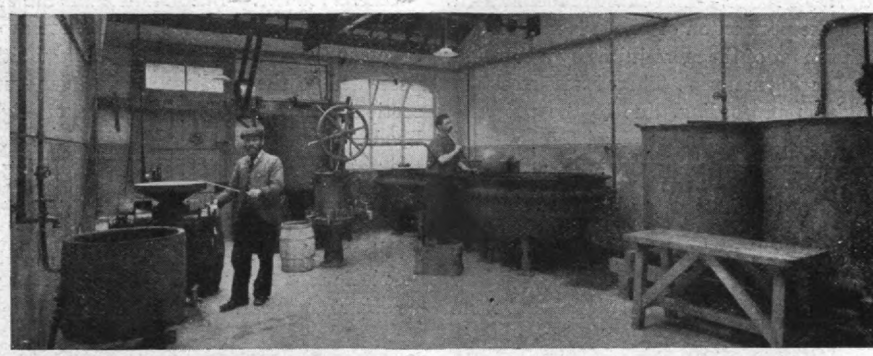


Fig. 23.—The Lard Room of an Irish Bacon Factory.

Where the stomach is not utilised in this way, it is generally cooked after being cleansed, and is sold as an ordinary food. The intestines also are frequently treated by being cleansed, cooked, and then sold as "chitterlings."

Glue, Jelly, and Fertiliser.—The hoofs of the pig when not sold in the fresh state are digested and converted into gelatine, which is used for a great variety of purposes. The bones and other residues find their way into the fertiliser tank, where they are first of all digested, so as to save what fat they may contain, and the balance is then dried into an impalpable powder, which is used for fertiliser. Any blood also which is not used for food purposes is generally worked up as fertiliser.

* "Accounts Relating to Trade and Navigation of the United Kingdom."

Pigs' Hides.—In Scotland particularly, there exists a considerable business in the tanning of pigs' hides. Curers of Wiltshire bacon do not remove the hide from the animal, but in the west of Scotland a considerable business exists in what is termed "rolled bacon," which involves the removal of the hides. These hides are very valuable for saddle leather, the binding of books, the making of purses and similar uses, and they are also used largely for the covering of furniture, for which purpose also the hair, which we saw is removed from the carcass at the very beginning of the manufacturing process, is also used. It is carefully freed from extraneous matter, and is utilised for the stuffing of furniture.

Everything in fact in connection with the pig is utilised, and there is no domestic animal which is of greater service to mankind. It seems strange, therefore, that although we utilise the pig and pig products so largely in the United Kingdom, there should be so little attempt made to increase our home production, and that we should go on from year to year relying upon the enterprise of foreign nations to supply our markets.

When speaking on another subject we saw that there was no provision in this country for giving technical instruction in connection with animal industries, and, as a consequence, these industries were very little understood. This seems to be at the root of the whole matter, as we unquestionably require in this country all these products which have been mentioned from time to time. It would therefore seem that the correct policy to pursue would be to institute such courses of instruction as would enable those who are associated with the meat industry fully to understand the technical processes connected with it.

This is a national affair, as it not only affects our food supply, but it touches also the question of employment, both skilled and unskilled, which would naturally follow upon the proper understanding of these various industries.

THE MYTH OF THE ARYAN INVASION OF INDIA.

By P. T. Srinivas Iyengar, M.A.,
Fellow of Madras University.

It is well known that most writers on modern history have not escaped the bias of their political or religious convictions, however impartial they have tried to be. In the selection of facts, in the method of marshalling them to point a moral, Hume was as much dominated by his Tory proclivities as Macaulay was by his Whig predilections. This applies in a small measure to ancient history, too. When the theory of the great civilised Aryan race was started, German patriotism claimed the Aryans to have been originally tall, fair, and long-headed, and the direct ancestors of the modern Teutons. French patriotism insisted that the language and civilisation of the Aryans came into Europe with the Alpine race, which forms such a large element in the modern French population; while the Italian Sergi, who belongs to the Mediterranean race evolved from an African stock, credits his own race with originating the Græco-Roman civilisation, and believes that the Aryans were savages when they invaded Europe. This colouring of history by the sympathies of the historian is not an unmixed evil, for to it we owe the rehabilitation of the character of Catholic sovereigns and statesmen by Lingard, and the explosion of the myth of the Saxon extermination of the Celts in England by leaders of the pro-Celtic movement of our own days. The eye of sympathy can alone pierce through the thick veil of interested misrepresentation, and emotion must co-operate with cold reason in the recovery of historic truth. It is not in history as in physical science where passion cannot blind the eye to facts. The Dravidians, the Dasyus, the Dasas—by whichever of these three names we may choose to designate the bulk of the people of India since historic times—have suffered from the misrepresentation of the Aryan Rishis, who composed the Vedas in the remote past, and of the ancient Indian commentators and modern European and American expounders of the sacred Scriptures of the Hindus. At the same time a mythical Aryan race has been built up out of scattered allusions in the Indian writings, and credited with the invasion of India, with the extirpation in some places, and absorption into the capacious Aryan fold in others, of the numerous tribes that occupied this vast continent. This theory appealed to the prepossessions both of those who believed in the repopulation of the world by the three sons of Noah, and of those who happen to speak a dialect of the "Aryan" speech. Being myself a Dravidian I propose to submit the theory of the invasion of India by the Aryan race, and of the extraordinary expansion of that race on Indian soil, to the test of reason inspired by sympathy for the Dravidian.

The comparative study of languages was born when it was discovered that the languages of

Hosted by Google

North India, Persia, Armenia, and practically the whole of modern Europe, all belonged to one linguistic group. The wide spread of these languages, now generally called the Indo-Germanic, was explained by the supposition that a race of people that spoke the parent form of these languages inhabited the regions beyond the Hindu Kush, and in prehistoric times sent streams of colonists to Persia, to India, to Armenia, and on to Europe. The flush of enthusiasm caused by such a brilliant recovery of ancient history by the study of languages was heightened by the emotional satisfaction due to the notion that the Germanic races that dominate the world to-day were of the same stock as the haughty Brahman of India, who has, like Saturn, gloomed by himself in the horizon of India for several millenniums, has guided its destinies in fields intellectual and political, and been responsible for the grandeur of its philosophy, and for the political ineptitude of its people. The name "Arya," which originally belonged to certain Indian tribes that followed the fire cult in the valley of the Punjab, and spoke an ancient form of the language whose later literary form was called the Sanskrit, the polished speech, was extended to this imaginary race, partly because Vedic Sanskrit—the language of the "Aryas"—was believed to be the most primitive form of the Indo-Germanic tongues, and also because the word "Arya," whatever its derivative meaning, meant "noble," and was, therefore, a fit designation for the great race that was believed to have civilised Southern and Western Asia and the whole of the European continent, and to lead the van of the world's progress to-day.

Anthropologists soon pricked this Aryan bubble, and the great Aryan stock that peopled such a large slice of the world's surface soon became a small tribe that "Aryanised" Eurasia —*i.e.*, transmitted its language and culture to other races. The original habitat of this much-shrunk tribe was shifted in 1878 from the regions round the Hindu Kush to the shores of the Baltic by Pösche, and in 1889 to Russia by Taylor. In 1901, Sergi maintained that the Aryans were "of Asiatic origin," and "were savages when they invaded Europe; they destroyed in part the superior civilisation of the Neolithic populations and could not have created the Græco-Latin civilisation." * In 1911, Dr. Haddon, the greatest living authority on ethnology, carefully avoided the mention of the word "Aryan" in his admirable account of "The Wanderings of People" in Europe. The "Aryan race" has been given the quietus so far as Europe is concerned.

The theory of the invasion of India by the "noble Aryan," and of the extinction in some places and the subjugation in others of the "savage Dasyu," was promulgated by Max Müller, Muir and other Sanskrit scholars in the middle of the nineteenth century, and has since been an article of creed with writers of the history of India. In 1891 and 1892 Risley attempted to supply this theory with an anthropometric foundation. Dr. Haddon summarises the results of Risley's researches in these words: "The Aryan type, as we find it in India at the present day, is marked by a relatively long (dolichocephalic) head, a straight, finely cut (leptorhine) nose, a long, symmetrically narrow face, a well-developed forehead, regular features, and a high facial angle. The stature is fairly high . . . and the general build of the figure is well proportioned and slender rather than massive."† These investigations were based chiefly on "the distinction between the fine and coarse type of nose," and on the theory that in India the nasal index "ranks higher as a distinctive character than the stature, or even than the cephalic index itself." This "Aryan type" is found in the purest form in the Punjab valley and, in other parts of India, is mixed with another type, called by Risley the "Dravidian type." To account for the existence of a "pure Aryan type" of non-Indian origin in the Punjab valley, Risley assumes that the "Aryans" must have moved into India with wives and children, "by tribes and families without any disturbance of their social order," at a time when North-Western India must have been open "to the slow advance of family or tribal migration." ‡ The previous inhabitants of the fertile valley of the Five Rivers politely retreated before the advancing "Aryans," so that the purity of the "Aryan type" might not be polluted; and when the "Aryans" had moved into the Punjab, an obliging Providence ordered that the North-Western frontier of India should be "closed to the slow advance of family or tribal migration." Granting that all these miracles took place four thousand years ago, does subsequent history help us to believe that this Aryan type has remained unpolluted in the Punjab? Innumerable races have poured into India through the north-west in historic times. Persians, European Greeks, Bactrians, Scythians,

* Sergi, "The Mediterranean Race," p. vi.

‡ "Imperial Gazetteer of India," I. p. 302.

Hosted by Google

Huns, Afghans, Tartars, and Moguls, have all invaded India and settled in larger or smaller numbers in the Punjab, and been absorbed in its "Aryan" population. It requires great scientific hardihood to maintain that the nasal index of the Punjabi has remained unaffected by this age-long welter of races.

Apart from the measurement of noses, the only other source of information regarding the "Aryans" of India is the Mantras of the Vedas of the Hindus. These Mantras were composed by Rishis belonging to tribes who called themselves "Arya," and who called certain other tribes "Dasyu" or "Dasa." In later days "Arya" meant "noble," and "Dasa" meant "a slave," but it is not possible to find out with certainty what these words meant originally. The Arya and the Dasa fought with each other frequently; but as frequently Dasa tribes were auxiliaries of Arya tribes in fights among themselves. None of these conflicts appear to be incidents of a war of invasion. The Aryas do not speak of themselves as invaders gradually driving the aborigines before them, and wresting their land from them. There is no trace of the inveterate habit of people settling in a new land, that of importing into the land of their adoption geographical and personal names from their far-off original homes. In the Vedic hymns there is not even the slightest reference to or memory of any land outside India which the ancestors of the Aryas inhabited, no hint of the route through which they came to India, no phrase reminiscent of any foreign connection. Nor is there anything to indicate that they were gradually or suddenly moving hordes; the Aryas of the Vedic Mantras speak of themselves as people living in the Punjab valley, leading a settled life in towns and villages, ploughing the soil and tending their numerous herds of cattle. Their kings, petty chiefs, lords of towns, and heads of villages, their village assemblies, political and religious, their irrigation canals and their roads, their threshing-floors and water-troughs for cattle, all indicate that the Aryas lived in an organised society in the Vedic times. Nor were the Dasyus savages; it is true the Aryans do not refer to them in complimentary terms. But even from the contemptuous references to the Dasyus in the hymns of their Aryan enemies, we can easily infer that they were not savages, but lived like the Aryans in towns and villages. They owned many castles built of wood like the castles of the Aryas. Their chariots, horses, and cattle proved a standing temptation to the Aryas to attempt to raid them. Thus all the available evidence shows that the Dasyus were not savages, but at least as civilised as the Aryas. There is nothing in the Mantras from which the physical characteristics of the Aryas or the Dasyus can be inferred. There is a solitary word (*anasa*) used in reference to the Dasyu, which has been variously interpreted as "mouthless," or "faceless," or "noseless," and some scholars believe that this refers to the nose o the Dravidian, "thick and broad," and the formula expressing its proportionate dimensions, "higher than in any known race, except the Negro."* There are also references to the "black" colour of the Dasyu; but, in some passages, this certainly refers not to the human enemies of the Aryas but to demons whom they dreaded, and, in others, it is not easy to decide whether the word is used metaphorically or literally. To construct theories of racial characteristics on the shifting foundations of solitary phrases of very doubtful import, and in the total absence of any other evidence, is speculation run mad.

The only certain difference between the Arya and the Dasyu, frequently referred to in the Mantras, is one of cult. Whatever the etymological meaning of the word "Arya" may have been in the Mantras, Hindu commentators on the Veda, from the authors of the Nirukta down to Sayana, have explained it as "the son of the lord," "the wise performer of the (fire-)rites," "wise worshippers," "practisers of fire-rites," "he who has attained a high position through the performance of fire-rites." On the other hand, innumerable passages in the Mantras describe the Dasyu as "devoid of (fire-)rites," "opposed to the (fire-)rites," "without Indra," "offerers of worthless libation," "fire-less," etc. From this it is evident that the Dasyus incurred the hatred of the Arayas, because they did not worship the Aryan god Indra, and did not, like the Aryas, offer sacrifices through Agni, the fire-god, the mouth of the Aryan gods and the mediator between them and their human worshippers. The Dasyus, like the Aryas, killed animals in sacrifice to their gods, and we may presume that, like the followers of many modern non-Aryan Hindu cults, they poured the blood of the slaughtered victims at their altars. The Dasyus must have hated the fire-rites of the Aryas as a strange innovation, and they are described as "revilers" of the (Arya) gods and rites, and are said to have frequently interrupted their

* Haddon, "The Study of Man," p. 104.

Hosted by Google

performance. The Nirukta defines a Dasyu to be one that "destroys fire-rites." Besides offering animal sacrifices through fire there was a special libation that distinguished Arya worship. More than the flesh of bulls and goats, Indra, the Arya god, loved the intoxicating juice of the soma plant,* and his worshippers, inspirited by liberal draughts of soma juice, ventured forth to raid Dasyu settlements, and bring back their cattle and their women as prizes of war. In comparison with soma, the offerings of the Dasyus to their gods were regarded by the Aryas as "worthless oblations." The Aryas also frequently refer to the Dasyus as "prayerless," "enemies of prayer," "those that do not employ hymns." This indicates another line of cleavage of cult between the Aryas and the Dasyus.

All Aryan sacrifice, of animal or of soma, of corn or of cake, was accompanied with recitations of "prayers," either composed for the occasion or taken from a pre-existing stock of Mantras. These Mantras were composed in an early literary form of the tongue that later gave birth to classical Sanskrit and the many vernaculars of North India. This tongue must have been the language of the Aryas, and we may assume that the Dasyus spoke dialects other than those of the Aryas. Besides the Indo-Germanic, there have existed in India from early times dialects of two other linguistic families, the Dravidian and the Munda. Though there is nothing in the Vedas to indicate that the people there called Dasyus spoke these and not the dialects of the Aryas, yet we may assume that the fire and soma cult of the Aryas was exclusively associated with Vedic speech. This is by no means certain, because the non-Aryan Hindu cults in which animal sacrifices are offered to gods not through fire exist to-day as much in those parts of India where Indo-Germanic dialects are spoken, as where the Dravidian and Munda dialects prevail. As these sacrifices were not and are not accompanied with prayers, we do not possess any evidence of the languages spoken by the followers of these cults in early times.

The fire and soma cult and the Vedic speech, then, and not differences of race, distinguished the Vedic Aryas from the Vedic Dasyus, in so far as we can judge from the Vedas. There remains to be discussed the question whether this cult and this speech were suddenly transplanted among the Aryas by any considerable body of foreigners, or whether they were slowly spread among them, undergoing changes in the process. The mere entry into a country of a foreign cult and a foreign tongue does not prove any appreciable ethnic disturbance of it. Dr. Haddon says: "It is astonishing with what ease a people can adopt a foreign language, which, however, almost invariably undergoes a structural and phonetic modification in the process."* It is well known to students of comparative grammar that the Vedic parent of Sanskrit is profoundly different from the original Indo-Germanic. In this, as well as in certain respects of structure, most of the Euro-Indo-Germanic dialects are nearer the original tongue than the Vedic speech. This shows that the Vedic tongue came to India as a foreign language, and underwent there a levelling down of its vowels and other alterations. Now, as regards the cults associated with this language. The soma plant is described in the Vedic Mantras as growing on distant hills, like those of Gandhara, and generally procured with some difficulty, and stored in a dried-up form as *charas* is to-day. In later times, when the centre of the fire cult shifted into the heart of India, the soma plant could not be procured, its identity was forgotten, and substitutes came to be used in its stead. The soma cult flourished in ancient times in Persia. We may thence infer that it found its way into India from without. But once it was introduced, it underwent a great development in this country. The Aryan Rishis appreciated the virtues of the soma juice so much that a large part of the Vedic Mantras is devoted to its praise; King Soma attained a distinguished position in the Vedic pantheon, and the soma sacrifice became the principal rite of the Brahman. The fire cult, like the soma cult, existed in ancient Persia, but with this difference, that to the Persians fire was so holy that throwing offerings into it would pollute it; so parts of the bodies of slaughtered animals were shown to the fire and thrown aside. As in India the offerings to gods were burnt out in the sacrificial fire, the fire cult underwent a fundamental change in this country. The gods of ancient Persia, as well as those of another people that spoke an Indo-Germanic tongue and "conquered Mitani (in the westward bend of the Upper Euphrates) by about 1500 B.C.," belonged to a stage of culture a little "earlier than that indicated in the *Rig-Veda*."† In other words, when the Vedic

* The soma plant has not yet been identified, but, judging from the methods of preparation of soma and its effects on man as described in the Vedas, it must be akin to the *bhang* (hemp) of modern times. The soma juice was drunk *without being fermented*, and mixed with milk or curds, or was cooked with flour.

* Haddon, "The Wanderings of Peoples," p. 10.

† *Ibid.*, p. 21.

Hosted by Google

tongue and its associated mythology reached India, gods like Mitra and Varuna, who till then had been supreme, retreated to the background, and their place was taken by Indra, the god *par excellence* of the Indian Aryas.*

Very little of the mythology associated with the ancient Indo-Germanic speech seems to have reached India. The only god common to the Vedic Aryas and the races that spoke Indo-Germanic dialects in Europe is Dyaus, and Dyaus is scarcely worth the name of god in the Vedic pantheon, being so little removed from the physical sky. Then, again, Mitra is practically the only god common to the Vedas and the Zend Avesta, and is in both literatures a subordinate person. Indra, the chief god of the Indian Aryas, is a minor demon of the Iranian Aryas. Varuna was unknown in Persia. All other Indian gods are of pure Indian origin, Rudra, Vishnu, Aditi, Maruts, Asvius, Ushas, etc. The name of the fire god, Agni, is also Indian, though evolved from an Indo-European root, the corresponding Persian god being Atar. It is impossible to discuss here how many of the Vedic gods were borrowed from the people of India, and then "Aryanised," and how many were evolved on Indian soil from pre-Aryan sources latent in Aryan speech, but the fact is striking that so few Aryan gods came to India along with Aryan speech.

From this we see that the language and the cult of the Aryas were borrowed from without, and profoundly altered on Indian soil. If this cultural drift had been accompanied by any appreciable racial drift, if the cult and the language had been brought into India by any considerable body of foreigners, who formed a race by themselves, and lived apart from the native races, neither the cult nor the language would have undergone such serious alterations as they have, but would have remained relatively pure. Hence we may conclude, with a fair degree of certainty, that in the second millennium B.C. a foreign tongue and a foreign cult drifted into India, and were adopted by certain tribes, later called Aryas, among whom the cult and the speech developed in new ways, and distinguished the tribes that possessed them from the other tribes of this country.

Even among the Aryas this cult was but superimposed on, and did not oust, pre-existing cults. It mingled with the previous totemistic cults implying the worship of animals—like the cow, the hawk, and the serpent, of trees like the *ficus religiosa*, of hill divinities, and river goddesses; it also mixed with innumerable religio-magical practices based on animistic beliefs, all which are abundantly referred to in the Vedic Mantras, and are prepotent to-day in India. But the fire-priests, some of whom, like the Rishis, composed hymns and instituted rites, and others like the Hota, the Adhwaryu, etc., assisted at the ritual, dominated the land from early times, and secured the patronage of kings. As they alone have left literary monuments, they loom large in the early history of India; but we must not forget that the bulk of the people of India followed, and still follow, the non-Aryan "fireless" rites of the Dasyus, and the fire-rite was at no age more than the semi-esoteric cult of the few. The spread of the fire cult into the lower Ganges valley and into the Deccan has been mistaken by historians for the spread of the "Aryan race." There is no evidence of a racial dislocation in India in these early days. So far as is known the bulk of the people was stationary. The story of the "Ramayanam" has been by some interpreted to refer to an ancient invasion of Southern India by the "Aryans." But how the mythical defeat of a King of Lanka by a solitary ascetic prince, exiled from his kingdom, helped by his brother and by a South Indian monkey tribe, can mean the migration of a North Indian people, passes comprehension. In all the early books there is evidence of the spread of the fire cult and the gradual increase of the power of the fire-priest, but none of any racial drift. Even this gradual extension of the fire cult did not mean the adoption of it by the people, such as takes place when Christianity or Islam spreads in our days, but merely meant the predominance of the Brahman and the adoption of forms of State fire-rites like the *Rajasuyam* or *Asvamedham* by kings for special public purposes. The fire-rite could not spread among the people, for from pretty early times the Brahman alone was competent to act as the fire-worshipper, and kings could be admitted to the fire-worship, even in sacrifices peculiar to

* The comparative study of religion has brought out the fact that the movement of religious thought in early times was not from polytheism to monotheism, but the other way about, from tribal monotheism to inter-tribal polytheism. In his "Religion of Egypt," p. 4, Professor Flinders Petrie says: "Wherever we can trace back polytheism to its earliest stages, we find that it results from combinations of monotheism." The polytheism of the Vedas is one of the many proofs that the Vedas refer not to the beginning of any cult, but the culminating stage of many pre-existing tribal cults, which had coalesced chiefly out of political causes. This is the real explanation of the perplexing henotheism (as Max Muller called it) that runs throughout the Vedic Mantras. At the time of the composition of the Vedic hymns, the tribe that worshipped Indra seems to have acquired predominance over the tribes that worshipped other gods.

Hosted by Google

kings, only after being temporarily invested with Brahmanhood, and even they could approach only the outermost of the sacrificial fires, that at the entrance to the sacrificial hall. This fire cult gradually died out even among the Brahmans, and to-day but faint relics of it are followed in a half-hearted manner in Brahman homes.

But from early days the name "Arya" —which originally belonged to the tribes that had adopted the fire and soma cult—was transferred to the higher classes of the Indian peoples, who, whatever their beliefs and religio-magical practices, acknowledged the theoretical supremacy of the fire-priest; so much so that when Gatama Siddhattha founded an order of ascetics (*Bhikkus*) open to Kshatriyas, in imitation of the Brahman order of Sanyasis, his *dhamma* was called Ariya (Arya). When, in later times, modern Hinduism rose with its numerous castes each characterised by endogamy, and with its beliefs and practices conglomerated out of every cult that had grown in ancient India, the term Arya was extended to every clan and every tribe that could lay claim to a high social status, and could enforce that claim. And, lastly, when the theory of the "Aryan Invasion" of India was promulgated by European scholars, it was seized with avidity by the "higher castes" as affording a historical basis to their pretensions of superiority to other castes. And the result is that every member of every caste that calls itself "Aryan" believes that blue Aryan blood flows in his veins. Emotion plays a large part in the manufacture of history, and any theory that soothes the vanity of a people is straightway elevated to the rank of a fact; so to-day a scientific examination of the bases of the theory of a superior Aryan race is resented more in India than anywhere else in the world.

European Sanskrit scholars, who have mostly kept themselves aloof from the world's progress in the science of ethnology, still speak to-day of the "Aryan" invasion of India, and the supersession of the aborigines by the "Aryan," as if it were a fact. They do not realise that, as Dr. Haddon says, "the so-called Aryan conquest was more a moral and intellectual one than a substitution of the white man for the dark-skinned people—that is, it was more social than racial." But it is regrettable that Dr. Haddon, the cautious ethnologist, the most eminent authority on the social drifts of the world, should yet give his unhesitating adhesion to Risley's theory that "Aryans, perhaps associated with Turki tribes," moved with wives and children into the Punjab about 1700 B.C., and completely displaced the previous population, and, what is more curious, their noses have remained unaltered since, notwithstanding that the Punjab has been the cockpit of races since the dawn of history almost down to our days, thus setting at naught at the same time the evidence enshrined in the Vedic Mantras and the necessities of the geographic control of all human affairs.

When all is said, there may still remain in the minds of some the feeling of doubt how a cult or a speech can travel by itself. The fire cult and the speech of the Aryas must have come to India in the wake of a peaceful overflow of people from the uplands of Central Asia into the plains of India, or been the result of a peace-intercourse between the Indian people and foreigners. But theories cannot be built on metaphors, and there is absolutely no evidence at present to guide to a solution of the problem.

ALGERIAN WINE PRODUCTION.

The wines all along the coast of the Algerian province of Oran, when properly made, are of good quality, and greatly sought after from a commercial point of view. The wines produced from vines grown in the plains in the vicinity of Oran (red soil, clay and flint), are of average colour, and sometimes have a sharp taste. Those from the hills (clay and chalk soil) are finer in quality and stronger. To the west of Oran, the vineyards on the coast, and particularly those of Bou-Sfer, give wine of a superior quality. At St. Cloud (east of Oran), grape gathering commences earlier than elsewhere, and the wine shipped to France before others is used to freshen up the French wines of previous years, rendering them again fit for commercial purposes. The St. Cloud wines are strong and have a rich colour, but are sometimes a little sweet. At Perragaux the vines produce a larger quantity of wine, but the quality is below the average, and the greater part of it is distilled. The same characteristics which are more or less common to all the wines of the Oran district, are also to be found in those of Mostaganem. They are, as a rule, a little weaker, their colour is not so dark, generally they are of a more delicate flavour, and they have a decided taste of the fruit. In these different regions of the Oran coast, the wines are made from excellent grapes of perfect ripeness, but they are regarded as inferior to those of the Sahel, which are similar. This inferiority, according to the American Consular Agent at Oran, is due solely to the unfavourable conditions under which the Oran wine is made. The vineyards of the inland regions, Mascara, Tlemcen, and Sidi-Bel-Abbes, produce wines which are of decidedly finer quality; they also possess a stronger, more decided taste of the fruit, and are brighter in colour. Their

Hosted by Google

superiority is due principally to the altitude. In these high regions grape-gathering does not commence until the end of September or October. Fermentation being effected under more favourable conditions, the wines are of better quality. The wines produced in the district of Tlemcen are of great delicacy, and rich in colour. They keep well. The most important centres of production are Tlemcen, Mansourah, and Ain-Fezza. In the district of Sidi-Bel-Abbes, the vineyards are half in the plains, half on the hills. Some are exposed to the spring frost, which at times destroys all the young shoots. The Sidi-Bel-Abbes wines are good, fresh, and of a rich colour, which they retain fairly well. Those from the hills are the best. Apart from the vineyards surrounding the town of Sidi-Bel-Abbes, the most important places in that region are Sidi-Lhassen, Oued-Imbort, Sidi-Ibrahim, and Ain-Trid. The Mascara vineyards are old, but they give the best wines in the province of Oran, very strong, of excellent quality, mellow in taste, and of a rich velvety colour. The white wines on the hills (clay and chalk soil) are produced mostly by native plants that yield remarkably good wine, which is considered among the best in Algeria. The wines of Saida, with less colour, vie with those of Mascara, but the superiority is rather on the side of the latter. Between the wines of the coast and those of the inland region, are those of an intermediate section, of which the town of Ain-Temouchent is the centre. The vineyards there, owing to the fertile volcanic soil, the situation and the altitude, can be compared with those of Sidi-Bel-Abbes and Mascara. The wines possess a high degree of alcohol, and are of a bright colour. They have the same defects as the wines of the coast but to a smaller extent, but they have not the same amount of acidity. The best places for their production are Hammam-Bou-Hadjar, Les Trois-Marabouts, Sidi-Daho, and Chabat-el-Laham. The production of wine in 1910 amounted to 58 million gallons, distributed as follows:—Oran, 38 millions; Bel-Abbes, 14 millions; Mascara, 3 millions; and Tlemcen, 3 millions.

THE RUBBER INDUSTRY OF THE CONGO FREE STATE.

The Belgian Government is making a special effort to encourage to the utmost the cultivation of rubber in the Congo Free State. Three expeditions went out in 1911 to the district of the Equator and discovered several tracts which seemed to meet all the requirements necessary to the cultivation of the *Hevea brasiliensis* (Para rubber). At the same time, the planting of hevea had already been tried in the five stations of the Bangala and in two stations of Stanleyville. The American Consul-General at Antwerp says that some of these plants, ten years old, have now reached the period of seed-bearing. Last year a considerable number of seeds were harvested and used immediately; the surplus seeds were held at the disposal of the natives and private individuals who solicited them. Experiments in tapping recently made at the Botanical Gardens of Eala, on hevea trees, six and a half years old, gave 515 grammes (1·13 lbs. avoirdupois) of dry rubber per tree. Other experiments in tapping made elsewhere gave excellent results—for example, at Boma, Kitobola, Coquilhatville, Bambili, and Niangara. It was found that coagulating the rubber sap by plunging it in hot water still gave the best results, and is much more effective than the slow process of allowing it to settle. The cultivation of several other species of rubber trees is being experimented with, but none equals the *Hevea brasiliensis* in point of production, growth, and quality. It may therefore be taken as settled, says the Consul, that the *Hevea brasiliensis* is the best adapted for cultivation wherever the rainfall is sufficient for its growth. With regard to Congo rubber, there is a constant demand for the highest grades, which, however, are becoming very rare; and one of the first effects of free competition would seem to be a notable lessening in the care given to harvesting and coagulating the rubber. The greater part of the Congo rubber imported into the Antwerp market comes from districts given up to private collection. It is feared that incessant harvesting of rubber in the Congo forests will impoverish the growth. Rubber experts therefore strongly advocate the systematic and well-organised planting of rubber trees, not only by the public authorities, but also by private individuals. As yet, the trade has not decided upon the best form in which the crude plantation rubber should be presented for sale.

THE STRAW BRAID AND STRAW HAT INDUSTRY OF TUSCANY.

The manufacture of straw hats and hat braid has been a flourishing industry in the province of Florence for more than a century. At present over 90,000 workers are employed in making, gathering, sorting and shipping the hats and braids from this district. In the province of Florence are upwards of one hundred factories devoted to braid work, and more than thirty making trimmed and untrimmed hats. Only some 4,000 persons are regularly employed in these factories. The outside workers are comprised under two headings, which refer only to their manner of living — 65,000 are "pigionali," *i.e.*, live in rented houses, usually near some factory, and 19,000 are "coloni," *i.e.*, tenants of small farms worked on shares. More than 56,000 women and 26,000 girls under age are engaged in straw work. They work for the most part at home, and the making of hat braid is, in the case of "coloni," done in addition to the usual work of the day. The most important branch of the local straw industry is the working of "paglia Fiorentina," or "nostrale," from which the famous Leghorn hats are made. The braid used in Leghorn hats is composed of thirteen threads. The manufacture of hats from "paglia nostrale"

Hosted by Google

is essentially a Florentine industry, and one in which there is no competition abroad. It is customary to order these hats by the number of "giri" or widths of braid to be used. The person making the braid then winds and sews the widths until the requisite number of "giri" has been reached. Ordinarily, Leghorn hats are sold in their natural colour, which is a light yellow. Some also are bleached by a process of washing followed by six or seven weeks' exposure to the sun. "Paglia nostrale" is also made to some extent in braids of five and seven threads. These lighter braids are used in the manufacture of broad-brimmed hats for women. In the Emilian Mountains, a straw, different in type and finish from the Florentine, is very largely worked. The hats of this straw in and around Bologna and the neighbouring villages of Monghidoro, Monzani, Lojano, Monteruggo, Filigare, etc., are called "punta" to distinguish them in the trade from the Florentine "nostrale" hats. This straw is plentiful in the Emilian Mountains, and is much rougher and coarser than the Florentine straw. Formerly "punta" hats were exported in their rough form, but of recent years they have been forwarded to the Florence district to be properly finished for the market. The finishing process renders them more saleable, though it increases the cost of each hat. Another important straw worked in Florence is called "truciolo." It is a woody product, not native to the district but grown in Russia, and made into threads of various sizes in Bohemia. Locally the "truciolo" is plaited into different types of braid. Another foreign straw worked is "japon." Work in this straw is ordinarily limited to braids, but some few exporters make up a considerable number of fancy hats for women in accordance with the fashion of the moment, in order to take advantage of the cheap hand labour in the district of Florence.

CORRESPONDENCE.

A SACRED PEACOCK.

The gift to the British Museum by Mr. Schwaiger, of Delhi, announced in the *Times* of July 8th, of "A Sacred Peacock"—it being "a steel-wrought peacock," believed to be the *Malik Taos* [ταῶς of Aristophanes and Athenæus], *i.e.*, "The Lord Peacock," or *Malik al Kuwat*, *i.e.*, "The Lord Angel" of the Yezidis, or so stigmatised "Devil-Worshippers" of Mesopotamia—has created so lively an interest, that I am encouraged to contribute a passing note on the subject for the *Journal* of the Royal Society of Arts.

The best account of this strange sect, whose religion is a jumble of paganism and Judaism, and Christianity, and Islamism, is still that given in his various volumes published from 1843 to 1853 by Layard, who visited these Khurdish people in their most eldritch abode and chief centre of worship about the Sinjar Mountain, near Mosul; the characteristic brass work of which town, the modern representative of ancient Nineveh, goes to this day throughout Syria by the commercial denomination of *ninavi*. Layard graphically describes their white-spired "Temple of the Sun," Shaikh-Shams [compare "Beth-Shemesh" of Joshua xv. 10, xxi. 16, the modern Ain-Shems, *i.e.*, "Well of the Sun," and xix. 22, and 38, both unidentified, and Jeremiah xliii. 13, identified with On, the Egyptian Heliopolis], and the drove of white bulls attached to it. Shaikh Shams is, of course, the analogue of the Babylonian Shamas, the brother and consort of Ishtar [Ashtaroth], as Shaikh Sin is of the Sabæan, and Chaldæan, "Moon-God," their father, who is said to give his name to Mount Sinai; although I myself incline to the assumption that the latter derives its name from the scrubs of Senna [*sanna*] to be found along its sequestered gullies, and adown its sun-scorched slopes. The river Indus is named also Abba Sin, but Sin here is a clipping of Sindu, the Indian variant of Hindu, meaning simply "water," or "river."

As to the suggestion of "A Sacred Peacock" being an idol of the Yezidis, it is material that its "provenance" should first be indisputably proved, and its history traced back to a date before the establishment of British rule, and consequent generation of forged "antiquities," in India. Had I been shown the illustrations of it in the *Daily Graphic*, the *Daily Mirror*, and the *Daily Mail* of July 9th, without knowing anything of the attribution to it, in the *Times* of July 8th, of an Euphratean source, I should have said that in all probability the place of its production lay in the Punjab and at Lahore; and I would further have ventured to hint that at some time—any time between Arungzib and Nadir Shah—it had possibly been in the treasured possession, as a tribal god, of one of the great princes of Rajputana; for they all worship Karttikya, the Hindu "God of War," in his name of Kumara, "The Boy," "The Prince," and in the very form of a peacock, called by them Paravani [? "of the Spread-fan"; compare also the Latin "pavo" and "pavoninus"], the *vahan*, *i.e.*, "vehicle" [compare "van"] of Karttikya, whose consort is Sina. This peacock is also used as an armorial bearing by many of the Rajputs. Surely, if the so said "Sacred Peacock" in the British Museum had been of Euphratean origin, it would have been fashioned more after the model of the bird-crowned brazen lamps of the temples of South-Western and Southern India, which, like so much of their furnitures [utensils, hangings, etc.] are obviously of Assyrian, and earlier Babylonian, and yet earlier Chaldæan inspirations.

The peacock, in Hindu mythology, is also the *vahan* of Sarasvati, the consort of Brahma, and "Goddess of Learning," although it is sometimes replaced by a goose! and peacock's feathers are everywhere in India used in exorcisms and other magical rites.

Hosted by Google

The earliest notice in Europe of the peacock is in the passages in Aristophanes [444–380 B.C.] alluded to above:—"Acharnians," line 63: "I'm sick of ambassadors and their peacocks"; and "Birds," line 269: "By Io!—surely not a peacock?" Athenæus is not worth quoting in the present connection.

As to the etymologies referred to above, the Latin "pavo," in Old Latin "pavus," is but the Greek ταῶς with the "t" changed to "p," which becomes, through the Latin of about A.D. 600, "paonem," the Spanish *pavon*, and French *paon*; and through Teutonic channels the German *pfau*, and Old English *pawa*, and our new English peacock, pea-hen, and pea-fowl—all these [and the Persian *taos*] originating in the Tamil *toggei*, the *tukkyim*, as is held, of 1 Kings x. 22, and 2 Chronicles ix. 21: "Every three years came the navy [or "ships"] of Tarshish [of the Phœnicians] bringing gold and silver, and ivory, and apes, and peacocks" [from Ophir, *i.e.*, the "Orient," including India].

Finally, the arts-craftsmen of North-Western India are exquisite—it is in my heart to say, per-exemplary—forgers of "antiques" of every description. Sir Bartle Frere, in 1876, brought home from India sixty gold coins, as of the Bactrian Greeks. Every one of them was a forgery. Later, several hundreds of copper, and silver, and gold coins, said to be of the Bactrian Greeks, were submitted to me; and again all the really interesting ones of the collection were forgeries. A grandfather will forge the coins, and at his death make them over to his son, with instructions, at *his* death, to hand them on to *his* son, for sale to the good English and better American "curio hunters."

GEORGE BIRDWOOD.

NOTES ON BOOKS.

MODERN PRACTICAL DESIGN. By G. Woolliscroft Rhead, R.E., Hon. A.R.C.A. London: B. T. Batsford. 7*s*. 6*d*. net.

This is a very comprehensive volume, dealing with plant-form as a basis of ornament, and the ornamental filling of given spaces as well as design for various crafts and processes of manufacture. Mr. Rhead is one of the examiners to the Board of Education, and he evidently knows what has up to the present time been expected of students who sit for the design examination, and has produced a practical and, in the main, a trustworthy text-book for their use. The book is well got up, and the numerous modern examples of craftsmanship with which it is illustrated are interesting and well chosen; indeed, the section which deals with craft work, though the limitations of space prevent it from being very full, should prove a useful introduction to the various processes—woodwork, metalwork, book decoration, pottery, and stained-glass making, etc., described in its pages.

The chapters devoted to design and space filling are, however, far less satisfactory. The author is evidently an enthusiastic admirer of nature, and he seems to think that natural forms can be turned into satisfactory fillings for panels, and even into designs for borders and repeating patterns, with far less treatment and adaptation than really goes to the making of a design worth the name. It is a common failing with students to imagine that in nature they have to their hand ready-made ornament, and that a careful study from nature can be worked up into a pattern. They want teaching that all that nature offers is suggestions—the raw material which has to be transformed into a design by the mind and hand of the artist. Mr. Rhead's book will not help them in this direction. Again, nature, it is true, is one of the chief sources, indeed the chief source of ornament; but it is not the only one. The designer who wishes really to know his trade must have studied, side by side with nature, the work of the masters who have gone before him, and in doing that he will discover not only how to treat natural forms, but also the beauty of various types of ornamental design into which nature enters but little, or not at all. With this side of design Mr. Rhead has apparently no sympathy—indeed, one might read his book and hardly be aware that it existed at all. In fact, we are led to suspect that, designer as he is by training, he is by instinct and conviction a lover of nature rather than of pattern.

HOW TO DRIVE A MOTOR CYCLE. By "Phœnix" (Chas. S. Lake). London: Percival Marshall & Co. 6*d*. net.

This little handbook is, as the author describes it, "a popular explanation of the handling and management of a motor bicycle on the road and at home." It is designed for those who, having some knowledge of an ordinary bicycle, now come into possession of a motor bicycle for the first time. Starting with the delivery of the new machine, Mr. Lake proceeds to describe the preliminaries to starting the engine, styles of mounting, the different methods of driving (with and without a side car), lubrication, roadside adjustments, and repairs —in short, all the points on which a novice is likely to need advice and assistance. Mr. Lake has a few words to say about the use and misuse of the "cut-out." Probably nothing has done more than this device to render the motor bicycle unpopular on the high road, and the noise which it makes is certainly such a serious objection that in the opinion of many the authorities would be justified in declaring it illegal. The difficulty is that up to the present it has been found impossible to devise a silencer which allows the engine to run very quietly and yet be free from back-pressure. No doubt this problem will be solved in time, but if in the meanwhile motor bicyclists would take Mr. Lake's advice, and only use their exhaust cut-outs when on the open road and with nobody near to be annoyed by the nuisance which they

Hosted by Google

undoubtedly create, we should hear a great deal less abuse of the motor cycle.

Mr. Lake, under his pen-name "Phœnix," is well known as a writer on subjects connected with motor cycling; he is also a practical motorist of great experience, and he has the gift of imparting information in a simple and lucid manner.

GENERAL NOTES.

Remains of Gigantic Animals.—The Natural History Museum has recently received some remarkable specimens or casts of specimens of extinct animals of exceptional size. One of these is a great horned dinosaur known as Triceratops. It is from the upper cretaceous strata of Wyoming, U.S.A., and its chief peculiarities are two enormous horns over the eyes and a great shield over the back of the skull, protecting the neck. The skull, with the shield, is about five feet long. The jaws are furnished with a large number of teeth, except at the anterior extremities, where they end in a kind of beak. There are also two extremely interesting accessions to the Museum which have not yet been mounted, and which will not be on view for some time to come. One of these is a cast of a bone belonging to an animal discovered in German East Africa. It has been presented by the Berlin Museum, where the original is preserved. The creature in question is a large dinosaur, and is known as Gigantosaurus. Of the particular individual of which the bone has been found only the humerus or upper arm and the scapula or shoulder-blade exist. The humerus is seven feet long. If the relative proportions of the limbs of this animal corresponded to those of the great diplodocus, which was found in America, and of the skeleton of which a replica, presented to the Natural History Museum by Mr. Carnegie, is preserved at South Kensington, the thigh bone of this East African dinosaur must have been twelve feet long. The other large animal to which reference is made above, and which is not yet available for inspection, is a dinosaur called Tyrannosaurus. It comes, like the first specimen mentioned, from the upper cretaceous beds of Wyoming. The Natural History Museum has a very fine cast of the skull of this creature, which was a carnivorous animal. The whole skeleton is in the American Museum of Natural History in New York. The skull of this dinosaur, which is probably the largest specimen of its kind known to science, is four feet four inches in length. The mouth opened for almost the whole length of the skull. The longest of the teeth are five or six inches in length. They are sharp and pointed, and the whole aspect of the beast is terrible, even at this distance of time. The animal, which had exceedingly small fore limbs, sat upon its hind legs like a kangaroo.

Continental Fruit Prospects.—The Board of Agriculture and Fisheries have received reports from His Majesty's Consuls on the condition of the fruit crops in certain districts in Germany, France, Belgium, and Holland. The Consul-General at Frankfort-on-Main reports that this year's crop of nearly all kinds of fruit in Germany will probably be a small one. The fruit trees and bushes have suffered heavily through the great drought of 1911, subsequently through the sudden change of temperature from warmth to intense cold in February, and finally through the spring frosts in April and at the beginning of May. In many districts a complete failure of the fruit crops is certain. In the district of Bühl, in Baden, the centre of the early plum cultivation, the loss sustained by the proprietors of vineyards and orchards is estimated at from £50,000 to £100,000. As to France, there is, generally, a great deficiency in every kind of fruit for exportation. There will only be available for export to the United Kingdom this year at most half the ordinary available quantities of pears, cherries, apricots, and apples; but of prunes, peaches and black currants there will only be one-third, if as much, and their price will probably be about one-third higher than last year. The plum crop will be bad. In Belgium prospects are very meagre. Early frosts destroyed the bloom, and the subsequent prolonged period of drought hindered the formation of the fruit. The crop is likely to be poor in quality and restricted in quantity. Fruit prospects in Holland are generally satisfactory.

The Production of Ipecacuanha in Colombia.—Ipecacuanha, a trailing plant, thrives best in clay soil along the banks of rivers. While it requires a great deal of moisture, it cannot live under water, and consequently in Colombia it is found in its best development in regions where the rainfall is abundant, but where the rivers do not overflow. The Sinu River is the ideal region for ipecacuanha. The plant is found in abundance from near the headwaters of this river to near the city of Monteria, about sixty miles from the coast, where the clay formation, which ipecacuanha seems to demand, stops, and below which point the river is subject to periodical overflows. The growth extends to several miles on each side of the river, and also to the more important tributaries of the Sinu, the Esmeraldas, Verde and Manso Rivers. In regions where the water is excessive, such as the valley of the Atrato, the plant, though found, has a poor growth and is of an inferior quality. In gathering ipecacuanha the whole plant is uprooted and the thin and soft rootlets are thrown away, and these discarded rootlets serve for reproduction, becoming in a year well-developed plants with valuable roots of their own. Ipecacuanha is not an object of cultivation in Colombia, though there is no reason why it should not be, except the fact that it is found wild in such abundance.

MAGNESIAN CEMENT IN INDIA.

By C. H. B. Burlton, C.E.,
Late Superintending Engineer, Indian P.W.D.

The largest known magnesite deposits in India are situated in the Salem district of the Madras Presidency, and these are owned and are being worked by the Magnesite Syndicate, Limited, London. Magnesia, or oxide of magnesium, the calcined product of the crude mineral magnesite, is manufactured on the spot, where the necessary kilns have been erected.

As the properties of magnesia in relation to its engineering uses are not generally understood, the object of this paper is to bring to notice an industry which can produce a building material cheaper than and, for certain works not under water, vastly superior to the best class of Portland cement, while recent experiments point to hydraulic possibilities.

The merits of magnesia are appreciated by the Americans, the Germans, and the British in the United Kingdom, who import it from the Salem deposits. But in India itself, where the deposits occur, magnesite is not in common use. Yet it may be conceded that the question of utilising the product of a native industry in preference to importing a foreign material depends on whether the native product is for the purpose required as cheap and as good as the foreign material.

The importation of products which do not show unquestionable superiority over those locally procurable should not be encouraged, for it is practically always advantageous for political and economical reasons to make use of the resources of the country concerned.

Sir Valentine Chirol has, in his "India's Unrest," emphasised the importance of investigating the resources of our Eastern Empire as a means of advancing its economic development, which is at present hampered by the preference given to imported goods. He even traces some of the disaffection in India to the inadequate support of native industries, on behalf of which the energy displayed by Sir George Birdwood and others has been conspicuous for the last thirty years, while the soundness of their views has been recognised officially. So far back as 1883, in fact, a resolution was passed by the Government of India that the utmost encouragement should be given "to every effort to substitute for articles now obtained from Europe articles of *bona fide* local manufacture or indigenous origin." Partial effect has, no doubt, been given to these views—as regards Madras at least—by the appointment of a Director of Industries in the person of Mr. Alfred Chatterton, an engineer of ability and high scientific attainments. But Mr. Chatterton's experiments have, it is believed, been confined almost entirely to the manufacture of goods in aluminium, a metal whose scope in India is limited at present to ornaments and vessels that are used for domestic purposes; whereas the magnesia industry of which Salem is the headquarters concerns works of general utility.

Particulars of the Southern India Deposits.

Salem, the principal town of the district in Southern India from which it takes its name, is situate half-way between Madras on the east coast and Calicut on the west, being about 200 miles distant from either port; and the deposits occur in two so-called "chalk hills," some 2,000 acres in area, lying to the north of the town of Salem and within a mile of the railway. The formation of these hills is mainly dunite with outcrops, beds, and veins of magnesite, from the white appearance of which their designation "chalk" is taken.

Mr. C. S. Middlemiss reported on these deposits in 1896, when Superintendent of the Geological Survey of India, describing the areas of the hills as "two such great intrusive masses of olivine-chromite rock and other olivine-bearing rocks, which, from their containing little or no felspar

Hosted by Google

or quartz, belong to the peridotite or ultra-basic group of rocks, such as dunites, picrites, etc. The rocks, owing to the unstable mineral olivine, have undergone enormous mineral change, whereby, first, the dunite became serpentinised more or less completely, and, secondly, the serpentinised product was further altered with the formation of magnesite, chalcedony, etc."

Use of Magnesia as a Cement.

But seventy years before Mr. Middlemiss wrote his report Dr. Macleod brought these deposits to the notice of the East India Company, from whom he obtained an honorarium for his researches on the value of magnesia as a cement, a great deal of which was used for repairing the counterscarp of the moat of Fort St. George, Madras. Subsequently, Captain—afterwards Sir Arthur—Cotton, R.E., followed on the same lines. It is, therefore, remarkable that India, with the material for an admirable cement available within her boundaries, should not make full use of it herself, instead of allowing it to be exported to other countries as she does.

Magnesia versus Portland Cement.

Lime has, of course, been used for ordinary construction from time immemorial. Sir Arthur Cotton used lime mortar only, or lime-surki mortar, even for his most important works; and for years afterwards the use of lime mortar remained unchanged, for Portland cement did not become general in India till the seventies. The great Godavari and Kistna Anicuts had no Portland cement in them originally, and these achievements will ever remain as standing memorials to the genius of Cotton and Orr. Gradually, however, Portland cement crept in, at first for use in wet foundations only, in respect to which it showed marked superiority to lime-surki mortar, which was the thin edge of the wedge in extending its use to work above water, and thus extravagantly adapting it to a purpose for which magnesia, a cheaper and stronger material, would have been preferable. Yet Portland cement is undoubtedly a boon. It gives a feeling of security, particularly in these days of reinforced concrete bridges and high masonry dams, which make tensile strength and resistance to crushing, matters of greater importance than they were formerly. The high dam for the water supply of New York has been built in with Portland cement throughout. But it will, it is believed, have cost forty millions sterling, and that in a country where the manufacture of the material is an indigenous industry. Nevertheless, it may be economically right to use Portland cement for certain purposes, in preference to magnesia in a country where the former is made, and if a satisfactory brand of Portland cement is now being, or can be manufactured in India—a brand good enough to pass the requisite tests—the use of it may fittingly receive encouragement for such purposes. But when Portland cement has to be imported over a distance of several thousands of miles, it behoves us to consider whether it is really necessary to use this expensive material as an all-round mortar, where special strength is required, instead of restricting its province to works for which a magnesia cement cannot be shown to be equally suitable.

On the other side, it may possibly be contended that India has no cause to complain; for India Office statistics show the amount of annual importations to be small. For example, in 1909–1910 and 1910–1911 there were respectively only 12,999 and 8,588 tons of Portland cement imported through the India Office, for the whole of India; and of these quantities only 915 and 40 tons respectively were taken for the Madras Presidency. But it is impossible that importations through the India Office stores can convey the slightest idea of the quantity of cement that finds its way into the Indian markets for Government works alone. It is true that if materials of external manufacture are required by the Public Works Department they must be ordered through the India Office. In point of fact, however, it is frequently impracticable to adhere to this rule; and when materials are wanted at short notice, as is often the case, it is customary with Provincial Governments to exercise their right of sanctioning purchases from local suppliers. Thus, the India Office returns give no indication of the actual quantities of cement imported from the United Kingdom. Nevertheless, the quantities must be larger than would be the case if the merits of magnesia were duly appreciated.

Dunite.

Magnesia is the calcined product of the mineral magnesite, which is derived from serpentine, while serpentine is derived from dunite—so called from the Dun Mountain of New Zealand—and dunite is a composition of olivine and chromite. The bulk of the rock of the chalk hills is dunite with intrusions of magnesite, comprising from a tenth to, in some places, as much as a half of the whole.

Mr. Middlemiss quotes the following analysis

Hosted by Google

of a specimen of dunite, as made in the Calcutta Geological Laboratory by Mr. Blyth:—

	Per cent.
Silica	39·10
Magnesia	48·26
Iron and aluminium, Manganese, Chromium, Moisture, etc.	12·64
	100·00

Specific gravity, 3·176.

Dunite from the Dun Mountain has been analysed by von Hochstetter to contain:—

	Per cent.
Silica	42·80
Magnesia	47·38
Ferrous oxide (after the chromite has been removed)	9·40
	99·58

And an analysis of oriental olivine, taken by Mr. Middlemiss from Dana's "Mineralogy," is as follows:—

	Per cent.
Silica	39·73
Magnesia	50·13
Ferrous oxide	9·19
	99·05

Specific gravity, 3·351.

Dunite we may practically assume to contain about 41 per cent. of silica and about 48 per cent. of magnesia, which, owing to the excessive proportion of silica, is a useless combination for a cement, as has been shown by experiments made last year by Mr. T. Bolas, F.C.S., F.I.C. But dunite and low grade, highly silicious magnesia—both of which had been calcined and ground separately, and afterwards mixed together with sand and water, but no magnesium chloride—attained, as a cement, a tensile strength of 201 lbs. per square inch and a compressive resistance of 2,290 lbs. per square inch, seven days after moulding; and this specimen was stated by the same chemist to have been distinctly hydraulic in setting. In the light of such a result further experiments with these materials are considered necessary.

Mr. Middlemiss has no doubt that the whole of the areas consisted originally of dunite, the olivine constituent of which passed into serpentine, while the chromite became segregated into nodules and veins. As serpentine is always produced by a chemical change in another mineral or rock, Mr. Middlemiss is undoubtedly right in his surmise. However, serpentine in its common form is too poor in magnesia, and too abundant in silica to be of use as a cement until it attains the form of magnesite, into which it is developed in the process of time.

The present supply of the magnesite is comprised in hillocks, which rise to a height of some 30 ft. above the level of the plain; and recent measurements show the existence in those hillocks of possibly a million tons of crude magnesite mineral, which might be quarried in open cut and thus taken out without mining. This would provide an output of 25,000 tons crude, or 10,000 tons calcined magnesia per annum for forty years, after which mining operations may be necessary, but nothing is yet known as to the persistence of these magnesite deposits in depth.

The Two Classes of Magnesite.

There are two important classes into which this magnesite is graded:—

(1) The second grade, containing from 80 to 90 per cent. of magnesium carbonate, and from 10 to 11 per cent. of silica.

(2) The first grade, containing over 90 per cent. of magnesium carbonate and about 1½ per cent. of silica.

Uses of Magnesite.

The uses of magnesite can be considered under the following heads:—

(*a*) Crude.
(*b*) Caustic, or lightly calcined.
(*c*) Dead-burnt.
(*d*) Fused.

CRUDE MAGNESITE.

At present there are but few direct uses for the crude magnesite; but its use as a source of carbon dioxide (CO_2)—a by-product in the manufacture of a calcined product—may be mentioned. Also the crude material may be cited as a convenient source of certain magnesium salts, of which the sulphate of magnesia (Epsom salts) may be taken as an example. It is further used for filling purposes, as in cotton goods, rubber, and paper, for which there may be a field in India. Crude magnesite has, after grinding, also been found suitable for use as a manure.

CAUSTIC OR LIGHTLY CALCINED MAGNESIA.

The caustic magnesia is produced by burning magnesite at a temperature of from 700° to 900°C. The magnesite may be either pure or moderately silicious; and it may, after calcination—in gas-fired shaft kilns and also in bottle kilns—be mixed with magnesium chloride in solution, and from ten to twenty parts of sand, by which process it becomes formed into a cement as hard as sandstone, and is rendered adaptable to various purposes, of which the following may be

Hosted by Google

mentioned: Plasterings, the manufacture of artificial stone, sand-bricks, slabs, tiles, concrete, magnesian mortar for magnesian bricks—though in that case not more than two or three volumes of sand should be used—woodstone floorings, sinks or gullies, tubes, receptacles for liquids, mantelpieces, garden furniture, and the manufacture of decorative and various moulded objects.

Magnesium Chloride ($MgCl_2$).

The preparation of magnesia cements of the Sorel type involves an admixture of magnesium chloride. Sorel, the originator of oxychloride cements, mixed the oxide and chloride of zinc together before he discovered the superiority of oxide-cum-chloride of magnesium.

Manufacture of Sorel Cement.

The object of mixing magnesium chloride with magnesia (MgO) is to impart to the combination high cementitious properties. The process of manufacture of the cement is as follows: The crude magnesite, either pure or laden with a certain quantity of silica and alumina, is first calcined in a gas-fired kiln, at a temperature up to 900° C. The lightly calcined or caustic magnesia, whose carbon dioxide has been partly driven off, is ground in a mill to the utmost attainable fineness; and a solution of magnesium chloride, together with an admixture of sand, is commingled with the finely-ground and lightly-calcined product in certain variable proportions. Of these, four parts by weight of the chloride ($MgCl_2$ 33 per cent.) solution, and fifty parts by weight of sand to five parts of magnesia may be taken as a typical example. It is important that no water other than that of the solution be used, as a rule, and in all cases the use of superfluous water should be avoided.

The mass commences to set at once, can generally be handled in under twenty-four hours, and in about a week is fit for testing.

Magnesium chloride required for use in India can be obtained thus:—

(*a*) It may be manufactured by adding burnt magnesite, or burnt dolomite, to calcium chloride, and the mixture is then treated with carbonic acid—a waste product of the industry—which causes the calcium carbonate to separate, and the magnesium chloride to remain in solution. This is the method adopted by Lanquetin, of Paris.

(*b*) The chloride can be imported in water-tight vessels from Stassfurt, where it occurs in the saline beds.

(*c*) It is obtainable in India itself from the bitterns, or sea-water residue, after the salt ($NaCl$) has been abstracted by crystallisation.

Imported Magnesium Chloride.

In ordering a consignment of magnesium chloride, precautions should be taken to secure a reasonably pure material; and estimates may be based on the assumption that one ton of a pure, anhydrous chloride dissolved in two tons of water will give a solution to be incorporated with the oxide—which may contain, after calcination, up to 20 per cent. of silica—in the ratio of four to five. On the other hand, it may be taken as certain that the magnesium chloride will be not quite anhydrous. It is indeed possible that crystals containing half their weight in water may be substituted for pure chloride; in which case the amount of water to be added for a solution will have to be reduced.

But it would be obviously extravagant to accept crystals that contain much water, and to pay for them and their carriage at the price of anhydrous chloride.

Scherer refers to the dehydrating process of the new Stassfurt Company, by which the water can be reduced to 12 per cent.; and he also refers to another industrial process, which gives an almost entirely anhydrous chloride. Thus, it would be possible to take necessary precautions in the matter.

Cost of Magnesium Chloride.

It is computed that European commercial magnesium chloride can be delivered at Salem at a *pro forma* quotation of £5 a ton; and, on the basis of a 33 per cent. solution, one ton of this chloride would, after delivery, have to be mixed with two tons of water; and thus, allowing a little for labour, a ton of that mixture might cost about £1 16*s*. Four-fifths of a ton—the proportion to be mixed with one ton of magnesia—would cost, say, £1 9*s*.; and, therefore, £1 9*s*. would be the sum to be added to the price of a ton of magnesia, if the plan of buying commercial chloride be adopted.

Sale of Magnesium Chloride by the Salt Department.

But it is hoped that the purchase of commercial chloride may be avoided, so far as the Government is concerned; for, in the event of magnesium chloride being obtained from the bitterns, the Salt Department might, by extending the salt industry to the development of magnesium chloride as a by-product, very reasonably derive a profit by selling the bitterns to the users of the cement.

Hosted by Google

The manufacture of salt in India is entirely a monopoly of the Government, who derive a large revenue from its excise. They possess along the coast of Madras factories where salt is extracted from the sea-water, and magnesium chloride might be obtained from these factories.

The sea-water is run into so-called pans—that is to say, shallow beds, where the water is evaporated by solar heat; thus the salt crystallises out, and leaves a residuum named bitterns. The salt is then collected, but the bitterns remain as a hitherto neglected product. Yet precautions have to be taken to prevent this waste product from passing into the hands of people who might glean salt from it, and so prejudice the public revenue. Under these, or, if necessary, additional preventive arrangements, it would be possible for the Government to dispose of the bitterns to the magnesia cement industry, stimulating thereby local trade in magnesia cement, which may assume large proportions.

With the co-operation of the Government of Madras, a practical experiment in the extraction of magnesium chloride from bitterns could be conducted at one of the salt factories in the south of the Presidency, where there is a maximum of heat and a minimum of rainfall. And a suitable place, where there is a salt factory, would be Vedarnien, south of Negapatam, for the site there is drier and hotter than elsewhere, while the rain is scanty and easy to avoid.

Bitterns.

With respect to extracting salt from the Madras bitterns, Dr. Ratton says that the manufacture of salt ceases when the hydrometer marks 32° Baumé, and the bitterns become practically a saturated solution of magnesium chloride; thus that is the stage at which the product should be used.

Although investigation as to the requisite strength may not have hitherto received such attention as is desirable, it is known that bitterns which register 32° Baumé consist of a nearly saturated solution, whose strength is 27 per cent. of magnesium chloride, for when this strength is reached there is only some 2 per cent. of sodium chloride remaining in solution.

Mr. Bolas has experimented with a 33 per cent. $MgCl_2$ solution, which contains one part by weight of anhydrous magnesium chloride to two parts of water, without losing its slightly pasty nature. This may be due either to a deposit of hydrated magnesium chloride in a crystalline or semi-crystalline form, or to the separation of an oxychloride of magnesium.

In dealing with bitterns it should be borne in mind that magnesium is not the only metal of which they may contain the chloride. It is naturally the business of the Salt Department to see that there is a minimum of sodium chloride left in the pans; and, since brine containing 27 per cent. of magnesium chloride does not hold in solution more than 2 per cent. of salt, and there appears little or no room for calcium chloride ($CaCl_2$), the inference may be deduced that such brine is virtually a solution of $MgCl_2$, but this is a matter which may require further elucidation.

However, if this surmise should be proved correct, it would be a point in favour of the Madras bitterns, for elsewhere there are bitterns which hold as much chloride of calcium as they do of magnesium. Fürer, in his "Salz-bergbau und Salinkunde," rather emphasises the presence of calcium chloride, which may sometimes be mistaken for magnesium chloride—a point to be considered in examining bitterns, since calcium chloride is apt to exercise unfavourable action as a retarding agent, but its real influence, whether for good or ill, is a question to be determined by further experiment.

Alternative Methods of Using $MgCl_2$.

The magnesium chloride can either be used in the form of a bitterns solution, or the water may be removed and the residual chloride transported separately to the work spot.

Cost of Magnesium Cement Compared with that of Imported Portland Cement.

As shown above, £1 9*s*., the price on a *pro forma* quotation of a one-third ton $MgCl_2$ admixture, may have to be added to the price of a ton of magnesia, which may be taken at £4—ground—on trucks at Salem. Nevertheless, the oxychloride, with its superior carrying capacity, is cheaper than Portland cement when used as a mortar.

A ton-and-a-third of magnesia cement would cost a purchaser £1 9*s*. plus £4, i.e., £5 9*s*., or at the rate of £4 1*s*. 9*d*. per ton, inclusive of fine grinding and packing the magnesia into bags, in which it will be kept separately until it has to be made into mortar. Then, after mixing the magnesium chloride solution with magnesia and sand in the necessary proportions, and also after mixing the Portland cement with sand and water in their necessary proportions, and

Hosted by Google

completing the mortar-making process, we obtain the following comparison :—

A strong magnesium oxychloride cement, containing ten parts by weight of sand to one part of fine-ground silicious magnesia and four-fifths of a part of $MgCl_2$ 33 per cent. solution, whose tensile strength was 269 lbs. per square inch after five days (Bolas), costs about 11*s.* per ton at Salem, inclusive of grinding and packing.

A strong Portland cement mortar, containing three parts by weight of sand to one part of cement, and having a tensile strength of 250 lbs. per square inch after twenty-eight days (British Standard Specification), costs about 16*s.* per ton at Salem. And it is observed that the proportions mentioned for the magnesia cement virtually correspond to those employed for the manufacture of artificial stone at Boston, U.S.A., which has been proved to be unaffected by any kind of climatic influence.

The proportions of cement to sand given for the Portland cement mortar are those mentioned by the Expanded Metal Company for armoured concrete. But such proportions remain fairly constant, even if the mortar be used for a wall plaster; whereas, if a magnesium oxychloride cement be used as a wall plaster, twenty parts of sand may be mixed with one part of magnesia which will considerably reduce the price of that cement. In fact, it might lower it to 6*s.* 6*d.* a ton, inclusive of fine grinding and packing into bags.

Last summer, in the course of experiments with magnesia, attempts were made to obtain a good cement by substituting various agglomerants for chloride of magnesium, such as borax with water, calcium chloride, sulphate of aluminium paste, sugar and water—some of the mixtures steamed and others unsteamed—and stirring up with each sample an admixture of ten parts of sand to one part of magnesia before moulding the whole into a disc; but the samples were all easily snapped with the fingers when tried, as was also a mixture of magnesia, sand, and iron perchloride (Fe_2Cl_6, 60 per cent. solution) weighed in the proportions of 5, 20, and 4 respectively, which had been eight days immersed in water. Yet it happened that a steamed sample, consisting merely of magnesia, water, and sand, could not be snapped until after a ten days' immersion. The caustic magnesia with which the experiments were made had been very finely ground in every case; and the apparent superiority of magnesia unassociated with any cementitious agent over magnesia more favourably placed must have been due to the steaming operation.

Crushing Resistance of Caustic Magnesian Mixtures.

In contrast to these failures, particulars of other types of magnesia cements, as given in the table on p. 857 are interesting, in that the cements display their powers of resistance to crushing after certain specified periods of immersion, periods that were continuous except for a few hours on February 24th, when the samples were taken out to be examined. These consisted of discs each 28 mm. in diameter and of the different thicknesses noted.

The magnesia with which the experiments were made was of two grades, one a moderately —MgO in the table—and the other a highly silicious grade. And both classes were the lightly calcined products of crude magnesite from Salem. In the former of these the original magnesite held 5 per cent., and in the latter 10·7 per cent. of silica. After burning, and the consequent expulsion of carbon dioxide, the proportions of silica left in the resultant magnesia will have been about doubled.

As against the greater purity of the 5 per cent. of silica grade of magnesite, the grinding of its product was not so fine as the grinding of the 10·7 per cent. grade.

Experiments with Dunite as an Admixture.

The dunite used was from Salem, and it was calcined at a temperature of from 700° to 800° C. Two samples of this dunite-cum-magnesia were moulded, one of which, not in the table, gave a tensile and crushing strength of 201 lbs. and 2,290 lbs. to the square inch in seven days, as previously noted. This sample consisted of 6 grammes of low calcined silicious magnesite, 6 grammes of low calcined dunite, 36 grammes of white sand, and 4 grammes of water, while the object of the experiment was to ascertain whether calcined dunite could serve as the "acid," or non-calcareous element in a cement.

The other sample is described in the table on p. 857, item No. (15). The sand used was fine "silver" sand in all cases. The silica and the alumina were pure laboratory products. And the perchloride of iron was the ordinary commercial product.

It will be seen that the oxychloride sand cements gave very good results only when agglomerants such as silica, alumina, or dunite were added. But the clay mixtures—items (12) and (13)—which contained no chloride, are, with

The samples were prepared and the crushing tests applied by Mr. Bolas.

their crushing resistances of 4,130 and 3,910 lbs. per square inch, comparable to pure Portland cement, and they are superior to Portland with an equal part of sand in association therewith.

Crushing Resistances of Portland Cement.

The following comparison is taken from Hurst's handbook, reducing crushing resistances in tons per square foot to pounds per square inch:—

	Lbs. per square inch.
Portland cement, pure, 3 months' old	2,364
„ „ and sand in equal parts, 3 months' old	1,555
„ „ „ „ 1 to 4, 3 months' old	1,120
„ „ pure, 9 months' old	3,733
„ „ and sand in equal parts, 9 months' old	2,815

The clay and the magnesia were in extremely fine powder—so fine, in fact, that the bulk of the particles did not exceed $\frac{1}{3000}$th of an inch in diameter, and the materials were rubbed together in a mortar; after which the sand, and then the water, were added and well incorporated with the other materials. The slightly damp products were finally malleted into circular steel moulds 28 mm. in diameter; and such was the general procedure adopted in the manufacture of all the other specimens.

However, tests with small pieces are certainly not so satisfactory as would be tests with larger blocks, which were presumably used for the Portland cement samples just quoted. Yet the margin between the magnesia-clay-sand mixtures and the Portland-sand-cements being so large, it is conceivable that even under parallel conditions the results would still be in favour of the former. But this is a matter for elucidation by further experiments, and these are now in progress. The methods adopted for carrying out the experiments under notice were similar to what is usual—that is to say, small stones (or coarse sand) were run down into a receptacle until the sample operated on was crushed under a system of levers.

In order that the tests might be as thorough as possible, the discs—as regards both oxychlorides and clay mixtures—were fashioned approximately into cubes, whose indicated resistances represent tests of single pieces, and not averages of a number of tests.

Clay Mixtures Compared with Oxychlorides.

On comparing the clay mixtures with the oxychlorides, or Sorel cements, it may be observed that, although the former did not carry as much sand as the oxychlorides, no such cementitious agent as chloride of magnesium was requisitioned to assist in their hardening; and a cement that can dispense with this important adjunct, while giving such a satisfactory result, is one of the highest importance.

Combinations (12) and (13), though apparently identical, differed with respect to the calcination of their clays. Of these the clay of the first item, which showed the greater strength, had been burned at a temperature of 200°, and that of the other at a temperature of 600°. The period of calcination was fifteen minutes in each case.

After twenty-four hours, sample (12) was immersed in water, where it remained till June 24th, 1911, or eight days; thus, its immersion in the following February and March was its second experience of water.

The Public Works Department might lay down a finely-ground magnesia-clay mixture as a mortar for concrete in foundations for some comparatively unimportant work, in the first instance, such as an irrigation distributary sluice or a road culvert. If the foundations were laid in a dry trench, which can often be done by means of a diversion cut, and kept dry for a week or ten days after completion, the water might then be turned on and allowed to cover them for a month, when it could be seen how they had stood the test.

Unlike the clay mixtures, the more quickly-setting oxychloride cements showed a tendency to soften in water; and, excellent as these oxychlorides are for work not under water, it is not, in the light of our recent experiments, considered desirable to subject such cements to the liability of absolute submersion, unless they can be periodically exposed to the air, so as to give them a chance of regaining their original hardness, which they do, as is apparent from the present state of the crushed specimens of our experiments, the pieces of which have become very hard.

It has been stated by various experts that magnesia cement is without hydraulicity; and such must necessarily be the case if the oxide be pure, or uncombined with a high percentage of active silica, for no cement that has less than 10 per cent. of silica, or an equivalent, in its composition will set under water. Messrs. Stanger and Blount say that magnesia cement is

Hosted by Google

merely hydraulic, inasmuch as when in water it does not disintegrate and crumble to pieces, but that it is not hydraulic in the sense in which the term is generally understood when applied to cements, for it is found that when magnesia cement—presumably after it is hardened—be immersed for any length of time it gradually decreases in strength until at the end of a period of twenty-eight days' immersion a briquette of one square inch section can be easily snapped between the fingers. As regards the last assertion, it is hereby contended that if very finely-ground magnesia be mixed with magnesium chloride and sand in suitable proportions, no ordinary man could snap a briquette—other than a dumb-bell shaped one—one square inch in section with his fingers. He might as well try to snap a piece of flint. The same authorities appropriately allude to the excellence of magnesia cement as a plaster, and to its capability of withstanding climatic changes, while they quote the well-known instance of a piece of magnesia plaster that had been applied to a building in Madras, where "it withstood the action of three monsoons and two hot weathers, and when last examined had not shown the slightest sign of being adversely affected, and was infinitely harder and more adhesive than the very best Portland cement plaster."

They then proceed to state that magnesia does not combine with the silicates of iron and alumina to form a hydraulic cement in the manner in which lime does. Here Messrs. Stanger and Blount would seem to be at variance with Redgrave, who claims, in his "Calcareous Cements," that the silicate and aluminate of magnesia produce a hydraulic cement which possess the same properties as, but is much stronger than, the corresponding lime compounds. And our experiments with the clay mixtures have a strong tendency to confirm this opinion. In fact, our series of experiments shows silicious magnesia to combine more strongly with clay than it does with magnesium chloride by itself; and if we knew more about magnesia-clay cements, it is possible that we might prefer them to the oxychlorides for all purposes, since clay is more easily obtainable than chloride. However, in the present state of our knowledge, it may be desirable to confine ourselves to oxychlorides for aërial work.

The Class of Magnesite to Choose.

With regard to selecting the magnesite, a consumer may argue that as ninety-five parts of magnesia will carry more sand than will eighty-five parts of the same, the best value is obtained by buying the purest grade possible; and if magnesia be the unit of purchase he is right. On the other hand, it should be remembered that reactable silica would appear to have a tendency to protect magnesium chloride against the effect of moisture, to which all works are subject. The highly silicious dunite admixture, item (15) in the table, should get much of the credit for the 3,940 lbs. per square inch compressive strength which was attained in that case. Again, the agglomerants hydrated silica, item (2) on the list, and hydrated silica plus alumina, item (3), caused the mixtures concerned to attain a crushing resistance of 3,910 lbs. and 4,340 lbs. to the square inch respectively.

It should be borne in mind that the amount of water used in a solution of magnesium chloride is important, for the water enters into combination, while the chloride merely assists the reaction; thus whether the magnesia be moderately pure, as in item (4), or strongly silicious, as in item (10)—to take two samples of equal mixtures—although the cement may be hard set, any water in which it may be immersed will extract some of the chloride and soften the cement. To obviate this disadvantage the Germans mix precipitated silica with the magnesia, as in item (2), in the proportion of 15 per cent. for choice; and they preserve the hydraulic properties of the cement by moistening it with a solution of magnesium chloride, while the hydrated or precipitated silica serves as a guard against disintegration by the action of water.

Resistance to Sea Water.

Scherer mentions that a cement so treated binds in about ten hours, and forms an exceedingly hard mass, which resists sea water; and he recommends as the best proportions for this cement 100 parts magnesium oxide, 15 parts precipitated silica, and 90 parts magnesium chloride solution (80 per cent. $MgCl_2$). He must mean 80 per cent. solution of the crystals. But he insists that the ingredients must be most intimately mixed, and the magnesia be absolutely free from carbonic acid. He quotes the tensile strength of this cement at 1,300 lbs. per square inch, which is by no means incredible, and it would take a large multiple of sand to reduce it in strength to Portland type.

Surki.

The tendency which the wash of water on the magnesium chloride has to militate against true hydraulicity, or the power of setting under

Hosted by Google

water *ab initio*, has a parallel in surki mortar. Surki, it may be observed, is powdered brick; and a mortar made up of equal parts, or otherwise, of surki, lime, and sand, being hydraulic, is largely used for wet foundations in India. But as water rises in the trench it drives out a great deal of the lime, which is consequently lost; it is accordingly desirable to lay the bottom six inches of concrete stones dry—that is, unmixed with mortar—as a base for the concrete-in-mortar foundation, and the experiments under review encourage the belief that, though a magnesia-clay mixture might be suitable to the situation, an oxychloride would be out of place except in combination with precipitated silica, either alone or in association with alumina, though possibly an admixture of dunite, as in item (15), might be substituted with advantage.

For anything short of a protracted immersion, nothing but sand need be added to the MgO and $MgCl_2$ solution, unless it be for something which has to be specially tough. In this connection Weber contends that agglomerates are, as a rule, tougher than unadulterated cements, for which reason he recommends what Scherer calls the MgOSiOMgCl for the manufacture of emery wheels—already mentioned—millstones, and artificial stone — ornamental and otherwise—which, moreover, forms an important industry in America, where they observe the following formula by Dr. C. T. Jackson, State Assayer of Massachusetts. This Eckel quotes as being suitable for window-caps, sills, steps, etc.:—

100 lbs.	of beach sand.
10 lbs.	of comminuted marble.
10 lbs.	of oxide of magnesium.
10 lbs.	of chloride of magnesium in solution (20° Baumé).
Total 130 lbs.,	yielding one cubic foot of moulded stone.

And Dr. Jackson adds, "For foundations and other plain, massive walls, the proportion of cement may be very considerably reduced, and the quantity of cobblestones increased"; which may be taken as evidence of the applicability of magnesia cement to concrete.

Lightly Calcined Magnesia in "Petrifite."

In the last decade of the nineteenth century a patent was obtained for a cement called "Petrifite," the composition of which consisted of nothing materially new. The cement was, in fact, just an oxychloride of magnesium with an admixture of acetate of lead; but the acetate of lead does not appear to have materially affected the main combination.

However, certain experiments made in 1897 by Messrs. David Kirkaldy & Son, as official tests for the Board of Trade and various railway companies, are instructive, in that they emphasise the superiority of magnesia cement. In giving the following particulars it should be noted that the specimens were cast without pressure:—

	Crushing resistance. Lbs. per square inch.
1 part of petrifite to 10 parts of sea sand, 30 days' old	3,405
1 „ „ 4 „ „ 30 „	9,000
1 „ „ 4 „ „ 10 „	8,095
1 „ Portland cement to 4 parts of sea sand, 10 days' old	734

It will be observed that the oxychloride of magnesium mixed with four parts of sand had practically attained its maximum compressive strength in ten days; and it may be mentioned that its tensile strength was correspondingly high, viz., 838 lbs. to the square inch in the same time, while that of the Portland was only 156 lbs.; and although the latter, being slower setting than the magnesian, will have continued to harden afterwards, the insignificant resistance to crushing which it showed must necessarily place it out of comparison with the oxychloride.

These experiments were made with sea sand. With three parts of pit sand to one part of the magnesia cement (presumably by weight), the resultant mortar showed a tensile strength of 946 lbs. per square inch, and the Portland cement mortar—mixed in the same proportions—one of 156 lbs., as in the former case; but the period was apparently seven days.

By substituting half a part of powdered chalk for half a part of sand the tensile strength of the petrifite mortar mounted to 1,217 lbs. in ten days.

As regards resistance to crushing, the one to three magnesian mortar, in combination with 8 per cent. of water, had a strength of 8,320 lbs.; and the one to three Portland cement mortar, in combination with 13 per cent. of water, had a strength of 635 lbs. But the period was probably ten days, which would suffice for the complete setting of a magnesium oxychloride cement, though not for a Portland.

To take one more example of an experiment with petrifite. Mr. T. J. Scoone, M.Inst.C.E., found that this material, made in a liquid form and mixed with other materials and placed under

Hosted by Google

water, would set quickly. He found that a small briquette became hard in three days, and that in seven days it became strong enough to test. This hydraulicity in magnesium oxychloride must have occurred in chemical association with silica, or the cement would not have set under water. If the magnesium oxide of the petrifite was pure the "other materials" must have included silica in a reactable form.

For works not subject to protracted inundation it is of little importance whether the oxide be pure, or silicious within limits. Either, in union with magnesium chloride, would be vastly superior to Portland cement. But for works under water, the latter will continue to hold its own unless further experiments establish the pre-eminence of magnesian-clay, or some other compound.

In considering construction, however, we exclude works which do not need a specially strong cement as a binder; for lime and surki are admirably adapted to ordinary building requirements. Moreover, these commodities are cheap, and deserve encouragement as indigenous products. But imported Portland cement is neither cheap nor indigenous, nor is there any reason to prefer it as a plaster, for instance, to magnesium oxychloride, a much cheaper cement for the same strength, or a much stronger one for the same price, according to the proportion of sand mixed with it. Furthermore, Portland, in common with magnesian and other cements, varies in quality; yet an importation through the India Office is reliable, for it will have been tested according to the British standard specification, and tensile strains have been found by the Director-General of Stores to vary thus:—

Neat cement . .	At 7 days.	450–650 lbs.
	At 28 days.	Up to 950 lbs.
(Average, about 500 and 650 lbs. respectively.)		
Sand and cement	At 7 days.	150–250 lbs.
	At 28 days.	250–400 lbs.
(Average, about 200 and 280 lbs. respectively.)		

Ferro-Concrete.

Such are the brands used for reinforced concrete, whose requirements are so exacting that attention might well be turned to the still more powerful local material, magnesia; but experiment is necessary to determine whether chloride of magnesium would injure the steel framework by chemical action. This might be done by the Public Works Department with a beam of magnesium oxychloride-cum-sand, and the internal steel-work protected by a coating of some anti-corrosive paint; such, for example, as might be made, according to Scherer, by adding mineral oil and 10 per cent. of caustic magnesia to the ordinary linseed oil paint, the idea being that the metal will be protected from rust by the neutralisation of the free acids of the paint.

Ligno-Concrete.

The merits of magnesium oxychloride as a cement for ligno-concrete work might also be tested with advantage. Mr. Gerald O. Case has, in a paper read before the Society of Engineers this year, drawn attention to the efficiency of timber as a reinforcing material, in respect to which it is sometimes used in America and Australia in preference to steel.

Carborundum as an Admixture to Oxychloride.

It may be desirable to use the precipitated silica admixture for armoured concrete. Such an admixture to magnesium chloride is, as mentioned above, recommended by Weber for the manufacture of emery wheels; and experiments made by Mr. Bolas in 1911 show the absolute suitability for emery wheels of a naturally silicious caustic magnesia—even with no precipitated silica—in association with carborundum, instead of sand or emery. The proportions in that case were:—

Powdered carborundum, which had passed through a sieve of 80 meshes to the linear inch	50 grammes.
Silicious magnesia, containing about 20 per cent. SiO_2, lightly calcined at 700°–900° C.	10 "
Magnesium chloride, 33 per cent. solution	8 "

The magnesite was calcined for an hour in the laboratory, crushed in a mortar, ground for an hour and a half in a Carr edge-runner mill, and thus brought into a condition fine enough to pass through a 240-mesh gauze, by which process the bulk of the particles became reduced to the diameter of $\frac{1}{3000}$ths of an inch.

The carborundum, was first mixed with the magnesia and rubbed in the mortar, after which the chloride of magnesium was added, the mixture well stirred, and finally malleted into moulds. Eight days later a specimen block of the agglomeration was hard enough to cut into glass, and it cut into quartz almost as easily as into glass.

By substituting sandstone, or flint, for carborundum, grindstones can be similarly manufactured; as can also millstones by using scrap, or the broken pieces of discarded millstones, for the purpose. Of course, the magnesite would be burned in a kiln, and a

Hosted by Google

period of twenty-four hours at a low heat might be necessary, for the reactable property of silicious magnesia is liable to be impaired by great heat.

Coal Briquettes.

The same proportions of the constituents of oxychloride cement, namely, ten parts by weight of silicious magnesia and eight parts by weight of $MgCl_2$ solution, will bind 200 parts by weight of small coal into briquettes, for which purpose caustic magnesia is, in virtue of its cohesion and elasticity, occasionally used, while the briquettes made through the agency of this cheap inorganic binder are remarkably solid, and thus suited to transport over long distances.

Xylolith, or Woodstone.

One more example of the use of lightly-calcined magnesia may be noted; namely, xylolith, or woodstone, which consists of an admixture of a sawdust to a magnesium oxychloride cement, and makes an admirable flooring which is jointless, noiseless, and dustless, and, being easily cleansed, is thereby rendered suitable for hospitals, bath-rooms, kitchens, etc.

If the flooring is to be outside, asbestos may be substituted for sawdust, for organic fillings are not weather-proof, whereas mineral mixtures are entirely so.

Great Importance of Grinding Fine.

From what we have said on the subject of caustic magnesia, it will be surmised that great importance is attached to the fine-grinding of the magnesia, and also of any calcined clay that may be used in a composition. It is, in fact, possible that any failure which may have existed in former days on the part of the natives to appreciate the value of magnesia as a cement may have been due to their inability to grind the product to the requisite fineness.

In the laboratory, where we deal with small quantities, it is possible to grind magnesia fine enough to pass through a sieve of 240 meshes to the linear inch. A grain of such powder may be measured by means of a ruling on glass; and Mr. Bolas used a spiral ruling 3,000 to the inch, which he employed as a provisional standard, so that with a microscope a single grain might be seen lying between two concentric circles $\frac{1}{3000}$th of an inch apart.

It is worth noting that, owing to the "bridging" and "clinging" action of the magnesia on the sieve, the particles which pass through are, on the whole, very much smaller than the meshes themselves. As a suitable regulator Scherer mentions a sieve of seventy-six meshes to the linear inch, with an allowance of 3 per cent. residue on the sieve, and this corresponds to the British standard of fineness for Portland cement, while the same standard prescribes as an alternative a sieve with 180 meshes to the linear inch, and a limit of 18 per cent. residue on the sieve.

A Portland cement that compares with these technicalities is used for reinforced concrete, for which it is good enough, since—mixed with three volumes of sand—it will have a tensile strength of 250 lbs. to the square inch in twenty-eight days; while its specific gravity will comply with a requirement of 3·15 at works, or 3·10 after delivery to consumer.

This closes our observations on the caustic or lightly calcined material, as applicable to engineering works. But engineering is not its only field. It is, for instance, possible to make use of lightly-calcined magnesia in the manufacture of paper from wood-pulp. Again—and this may be urged as a further incentive to co-operation on the part of the State—magnesia may be used as a basis for important disinfectants and bacteriocide preparations—as, for example, the hypochlorite, a salt which possesses bleaching properties. Furthermore, its extension to the manufacture of magnesium peroxide might possibly be encouraged, for magnesium peroxide, under the designation of magnesium "perhydrol" is now used for various medico-sanitary purposes.

DEAD-BURNT MAGNESIA.

Although dead-burnt magnesia has not such a variety of uses as has the lightly calcined mineral, its importance may be considered in one respect as even greater than the latter, in that it is most difficult—if not impossible—to find an adequate substitute for dead-burnt magnesia in the composition of a work which is required to possess great refractoriness against heat.

In this connection it may be stated that when magnesia has to be dead-burned it is preferable to select it from the purest class.

And the following analysis by Mr. H. H. Dains, F.I.C., may be taken as typical of the first grade class of Salem magnesite:—

	Per cent.
Silica	0·29
Iron oxide, Alumina	0·65
Manganese oxide	0·20
Lime	0·83
Magnesium oxide	46·42
Carbon dioxide	50·71
i.e. Magnesium carbonate	(97·13)
Combined water	0·16
	99·26

Hosted by Google

As a Lining for Basic Furnaces.

The selection of a pure class of magnesite is necessary when the magnesia is to be dead-burned, because the product will be required as a lining for basic furnaces, or for the manufacture of fire-bricks, both of which necessitate a highly refractory material; and the refractoriness of magnesite varies inversely with its percentage of silica.

Hitherto the use of dead-burnt magnesia has been practically confined to Europe and America, but now, thanks to the enterprise of Messrs. Tata, the demand is likely to arise in India as a lining for basic furnaces for the manufacture of steel, which are now in the course of erection at Kalimati.

Calcination of Magnesite for Dead-burnt Magnesia.

To obtain a ton of dead-burnt magnesia two tons of crude magnesite are theoretically required, on the assumption that the magnesium carbonate ($MgOCO_2$) consists of 50 per cent. magnesia (MgO) and 50 per cent. carbon dioxide (CO_2), each by weight, which is approximately correct. On calcining at a temperature of 1700° C. for a sufficient period, the carbon dioxide is expelled into the air, leaving the magnesia in a dead-burnt condition. But, in practice, it is necessary to use $2\frac{1}{2}$ tons of magnesite to produce one ton of magnesia, the extra half-ton being a provision to allow for loss one way and another. This shrunk magnesia has a specific gravity of 3·5.

Of course, as the magnesite does not actually hold 50 per cent. MgO and 50 per cent. CO_2, there must necessarily be a certain quantity of "impurities" deposited; and, as these tend to impair the refractoriness of the magnesia, the demand for the purest magnesite is persistent, especially as the impurities are not driven off, and are therefore practically double in the resulting product.

The undermentioned analysis of "Indian dead-burnt" calcined in a gas-fired kiln is by Mr. Dains:—

	Per cent.
Silica	4·38
Ferric oxide	1·02
Alumina	0·10
Lime	1·04
Magnesia	93·12
Loss on ignition	0·34
	100·00

It will be seen that a high percentage of magnesia is maintained, for the employment of a gas-fired kiln obviates such contamination as would occur with the ash if coke were the fuel.

Fire-bricks.

There is a demand in India for fire-bricks, which are always imported from Europe; whereas, with sufficient encouragement, the manufacture of fire-bricks might well be organised as an indigenous industry, since it is conceded that no bricks are so refractory as those of the magnesia class.

The following analysis is that of a fire-brick made from Indian magnesia:—

	Per cent.
Magnesium oxide	92·12
Iron peroxide	1·02
Alumina	0·10
Calcium oxide	1·04
Silica	4·38
Phosphates, sulphates and alkalies	traces
	98·66

This brick was made at Neath; but Mr. Dains quotes an analysis by J. W. Westmoreland, of a brick, likewise from Indian magnesia, which contained 93·94 per cent. of magnesia and only 2·60 per cent. of silica. Its specific gravity was 3·58.

MAGNESITE FUSED IN THE ELECTRIC ARC.

A more highly refractory magnesia may be obtained by calcining the magnesite in the electric arc at a temperature of about 3000° C., and maintaining a current of 3500 ampères at a pressure of 65 volts. This subject is fully dealt with in the "Transactions of the Faraday Society" for August, 1905, where it is noticed that Salem magnesite, which had been electrically calcined in Norway was, in conjunction with other magnesite products of Salem, awarded a gold medal at St. Louis, and highly commended by Mr. Edison as a refractory material of exceptional value. Another gold medal was awarded at the Franco-British Exhibition of 1908. Fused magnesia has a specific gravity of 3·58 (Dains).

Specific Gravity.

In dealing with the question of specific gravity, it may be noticed that the engineer determines the specific gravity of the mass, and the chemist that of the particles comprising the mass. Thus the specific gravity of a magnesian brick, reckoned at 2·5 by an engineer, would become 3·58 (Dains) under a chemist's manipulation. It was from the latter standpoint that Mr. Bolas obtained the

Hosted by Google

following as the results of his experiments last summer:—

1. Lightly calcined silicious magnesian cement, consisting of: Crude silicious magnesite, holding 10·7 per cent. of silica, 140 grammes; flesh-coloured clay from Salem, 35 grammes; mixed and ground to nodules of about $\frac{1}{3000}$th of an inch across. Heated and subjected to air-pump action. Specific gravity, 3·46.

2. Silicious magnesite of the same kind, but with no clay. Subjected to the same treatment. Specific gravity, 3·33.

3. High-burned magnesia from an almost chemically pure magnesite. Specific gravity, 3·45, which approximates closely to the 3·50 specific gravity as given by Mr. Dains, for the same class, in his lecture at Burlington House on May 3rd, 1909.

Another example of this kind indicated a specific gravity of 3·32 only, the lowness of which figure may have been due to the action of the air on the sample, for a thin layer was formed on the bottom of a bottle in which it had remained for some weeks.

4. Lightly calcined magnesia (in fine powder of course). Specific gravity, 3·57, which is practically the same as 3·58, given by Mr. Dains for artificial periclase.

It is conjectured, from these experiments, that the specific gravity, that is the specific density, of magnesia, is subject to little real variation, and, thus, such variation as is apparent from the figures quoted may be due to difficulties encountered in obtaining absolutely accurate results. Therefore, in the case of magnesia, the specific gravity scarcely gives a ready or certain means of forming an opinion as to the cementitious condition of the material.

With Portland cement it is otherwise. There the sintering of the materials results in a heavy product, the specific gravity of which may be accepted as an index of its cementing power; and in a routine testing laboratory the precise specific gravity can be easily determined, whether it be 3·10 or 3·15, figures insisted on by the British Standard Specification as a minimum; and figures which would allow a large margin for magnesia, whose specific gravity is invariably higher than these; while the rapidity with which an oxychloride magnesian cement sets, and attains its tensile strength, would seem to emphasise its suitability for reinforced concrete and other forms of construction, always provided adequate measures be taken to protect contiguous iron or steel from any corrosive action that magnesium chloride may possibly exercise.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

Conditioning Houses.—Upon the Continent there are at least eighteen public institutions to which textile materials may be sent in bulk for test and certification. There are nine in France, but in this country precision is less popular, and of fully equipped conditioning houses there is but one. Manchester has had its Chamber of Commerce testing-house since 1895, and its certificates are authoritative the world over, but this is a sample testing-station only. The single bulk conditioning-house is at Bradford, and is municipally owned. It has been at work for twenty-one years, and its premises are thoroughly outgrown and are being extended. The establishment was created to meet the demands of exporters, and only gradually have its services come into large use by parties to the home trade. Tests of many kinds are performed there, but tests for "condition," *i.e.*, moisture, form by far the main part of the work. In round terms the conditioning-house handles 100,000,000 lbs. of material annually, three-quarters of it being combed but unspun wool. It conducts nearly a quarter of a million tests a year. The method of testing for moisture is simple, and has been so organised that the ovens can be watched by girls. A pound sample is suspended from one arm of a balance, and hangs in an ascending current of air heated to 220° to 230° F. The loss of weight is noted, and when a constant level is reached the bone-dry weight is ascertained. To this result is added a standard allowance representing the normal regain, and the disparity between this and the observed loss gives the variation above or below correct condition. Cotton is credited with a regain normally of 8½ per cent., silk of 11 per cent., linen, 12 per cent., and wool 16 to 19 per cent., according to its state. These are percentages of the dry weight, and not to be confused with calculations on the gross weight. Wool of 19 per cent. regain is in correct condition when containing fractionally less than 16 per cent. of water. The allowances accord broadly with the common experience of the hygroscopicity of the several fibres, and are in international usage.

Motor-cars and Textiles.—The presentation of lengths of motor cloth to the King and Queen at Batley, gives a reminder of how textile industry is shaped by outside circumstances. The advent of the motor set in motion changes which most manufacturers have felt. Very early the taste for motoring began to destroy the fashion for elaboration in dress, so affecting some groups of mills adversely. Some amends were made by new demands for wind, weather and dust-proof garments, leading to the creation of new and various fabrics called by the name of motor cloths. Veiling assumed a new importance, and tweed caps became a necessity of motoring men. The old trade in horse-clothing has contracted, but a far from inconsiderable quantity of cloth is taken to equip

Hosted by Google

the motor-car. The mock-leather seats are cotton dressed on one side with a paste of viscose derived from wood-pulp. Some manufacturers are busied with little else than making strong cotton duck for imbedding in tyres. Motorists grumble at some of the tyre-fabrics supplied, but the manufacture receives pains to make the cloth strong initially and to prevent deterioration from wet. As the 60 lbs. pressure within the tyre is more than some steel boilers can withstand, occasional bursts are not inexcusable. Cotton, linen, jute, and even camel-hair are used in hoods for cars, and the business in knee-flaps, rugs, and floor-coverings is rather more than negligible to-day. Thus far aviation has produced no comparable changes. There is a demand, small but growing, for wing fabrics for aeroplanes, and for the most part this is met by foreign-made, light and strong cloth, manufactured from long Egyptian cotton.

Camel Hair.—It may be feared that not all products sold under the name of camel hair owe their origin to the camel, although some 8½ million lbs. of the authentic hair are regularly imported into this country, and some 5 to 6 millions are retained. The manufacture is a minor branch of Bradford activities, and is in comparatively few hands. The hair serves two distinct sets of purposes. On the one hand there is the consumption of the short hair for making soft, warm hosiery, and fleecy linings or fine Wilton carpets. Again, there are demands best filled by the coarse beard hair from the thigh, throat, and humps. Camel hair, its blends or substitutes, is much used for making mats or cloths for oil presses, machine belting, and to a less extent for motor-car hoods and golf bags. Where durability is the first consideration, the supply of camel hair is eked out by the coarsest wool, human hair or any available long and strong fibre. The mixture is combed and brought to a fairly uniform fawn shade in a dyeing machine, and then spun on worsted frames. The imitation is not necessarily inferior in point of strength to the original, and large quantities of it are made.

The Making-up Trade.—A trade saying has it that the eye is more easily cheated with the needle than the yardstick. Freely interpreted, this means that there is a better profit in selling garments than selling cloth; yet it is not noticed that textile manufacturers are going into garment making on their own account. More and more they are having to look to the maker-up for custom. The retailing of cloth by the yard is dying out, and the draper who used to sell dress lengths now sells ready-made costumes. Even children's clothes are largely factory-made, instead of home-made, and the great staple of the ready-made suit trade is suits for boys. Business in ready-made suits for men makes no great headway, but there are large developments in the factory tailoring of clothes cut to individual measure. Everyone has seen how ready-made cloaks and coats have come into favour. It may have been observed, too, how the clothing manufacturers, especially of Leeds and the Midlands, have pushed the retailer out and become their own distributors. Changes of this kind have necessarily had their effects upon the conditions of cloth manufacturing. The makers-up want principally cheap goods chosen rather for smartness of appearance than enduring wear. They want to buy at certain fixed limits corresponding with the stereotyped prices for finished garments, and they are closely tied to particular dates and seasons. The quantities are large, and on the whole the terms of credit are short, but the profits in selling are not high. It might have been expected that the general substitution of wholesale for retail tailoring, dress-making, and so on, would have tended to produce larger orders to one pattern. In some directions this may have been the effect, but it is one of which little is heard. Everywhere manufacturers can be found lamenting that orders are smaller than they used to be, and entail very much more trouble and expense in execution. It is clear that there are centripetal as well as centrifugal forces to reckon with. Demands are more diffused than ever, and the efforts of manufacturers who wish to differentiate their goods from those that the wholesale makers-up are selling are assisting to disperse demand over an ever wider field.

The Dyeing Industry.—While there are manufacturers who elect to do their own dyeing, the work is more generally put out to the commission dyers. The capitals of the "combines" in the dyeing trade are some index of the magnitude of this department of work, and in addition there are census of production figures to show that commission bleachers, dyers, printers, etc., do substantially eighteen million pounds' worth of work in a year. Combination in the dyeing trade has spelt centralisation. The work has been segregated in the combined works, so that as far as possible one branch is kept to goods of one class. Accordingly, there are works in which nothing is dyed except blacks, year after year, and others which treat only with colours. The arrangement permits of great economies, and is in striking contrast with that of fifteen years ago, when dyers got what work they could, and dealt with it as they were able, at whatever expense in change of routine. The unsyndicated dyers occupy a similar position to-day, and are called on to execute widely differing classes of work. Conditions allow of no waste of time, and a rare aptitude is requisite in making an exact match to a shade that has not been attempted before. Dyers vary in their methods, some of them trusting most to formulae, and others mainly to the eye. Formulae in a mixed dye-house are not an unqualified blessing, and off-hand judgments are satisfactory when the eye is good, and profoundly to the contrary when the dyer is not in the accustomed trim. In these circumstances it is being found well to simplify colour-matching by

Hosted by Google

restricting the choice of colours to three primaries, black and a few fine colours for use in screwing up the result to the desired shade. With a little practice it is easy to estimate the proportions of red, blue and yellow in a given shade, and easier to correct a fault when few and simple colours have been used. The restriction limits waste of colour and favours advantageous buying. As all who have touched them are aware, modern dye-stuffs are powerfully colorific, but there are individual dyers in the North of England whose affairs justify them in putting down contracts for as much as one hundred tons at once in one colour. Some of the combinations probably give out materially larger orders from their head offices, and mainly give them to the great German dye-ware firms, which in turn are members of combinations and parties to a "convention" for fixing minimum prices.

CORRESPONDENCE.

INDIAN RAILWAYS.

The subject of Indian railway extension is so important that I venture to ask you to find room in the next number of the *Journal* for this letter.

In the remarks I made on Mr. Neville Priestley's paper on Indian railways I stated that the only reason I was able to give for Government offering 5 per cent. on rebate terms to investors, was that Government had themselves grave doubts of the branch lines, open to construction by the public, paying 5 per cent. on the terms offered. Mr. Priestley, in reply, took exception to my attributing such "unworthy motives" to Government. The following will, I think, go a long way to prove that I had reason for what I wrote. The Karachi Chamber of Commerce have been urging upon Government the necessity of extending the metre-gauge railway from Hyderabad (Sind) to Karachi. In reply to the Chamber—with which reply the Government of India are "entirely in accord"—the Government of Bombay, in a letter dated April 19th, 1911, say: "I am to request that any further representation which your Chamber may desire to make regarding the extension of the metre-gauge, from Hyderabad to Karachi, may proceed on the basis of the line being constructed by Government as a State railway." With this letter is enclosed a copy of Paragraph 9 of the Railway Board's No. 59/14, dated June 25th, 1906, advising Government in this connection, which advice has been accepted, and is the reason for the decision to construct the extension by the State. The Railway Board say: "On question (2), viz., the agency which shall construct the connecting link . . . the Board are of opinion . . . that it should be made as a State railway for three reasons. The first is that it would be a *very profitable* one." The italics are mine. What is to be understood from this? Plainly it can only mean that, had it been probable that the extension would *not* have been "very profitable," private enterprise would have been allowed to construct it; being "very profitable" Government reserve it for themselves.

Writing in your *Journal* in 1895 on the rebate terms then offered, I remarked: "The truth is the Indian Government do not wish lines to be constructed by private enterprise. They have a very valuable monopoly and are by no means anxious that outsiders should interfere with their profits, or take the good things they hope in a few years to appropriate to themselves. Such feelings are, under the circumstances, natural, but it seems a pity that Government do not openly avow them, and thus save many would-be promoters the loss of time and money and the vexation of spirit that is the result of the existing system."

It appears that these remarks are as appropriate to-day as they were seventeen years ago.

J. FORREST BRUNTON.

NOTES ON BOOKS.

CHATS ON OLD JEWELLERY AND TRINKETS. By MacIver Percival. London: T. Fisher Unwin. 5s. net.

Of the admirable "Chats" handbooks on artistic furniture and personal ornament in course of issue by Mr. T. Fisher Unwin, this delightful volume, in octavo, of "Chats on Old Jewellery and Trinkets," by Mr. MacIver Percival, is of the widest interest and acceptability, not excluding Mr. Arthur Hayden's well-known "Chats on Old China." The guiding motive of the whole series, and its distinguishing merit, the honour of which belongs altogether to Mr. T. Fisher Unwin himself, is to serve the purposes of those who, mindful of the responsibilities involved in the spending of money, accumulate their artistic treasures not only for their own instruction, and pleasure in them, but as a sound investment, however inconsiderable, whether for their families or the nation. These "Chats" are, in short, all intended to be especially helpful to buyers and sellers; and naturally Mr. MacIver Percival's "Chats" recommends itself to a larger number of owners and producers, and middlemen and *virtuosi* than any others of its suite. But what makes this volume so valuable is that Mr. MacIver Percival is not only an experienced writer on its subject, and a recognised *connoisseur* in "Old Jewellery and Trinkets," but a practical jeweler himself, trained to the vocation at the "Central School of Arts and Crafts," and under the immediate direction of Mr. Alexander Fisher, Associate of the Royal Cambrian Academy, whose decorative work in sculpture, in gold and silver smithing, and in enamels and jewelry, has done honour to the artistic craftsmanship of the United Kingdom throughout the world. Mr. MacIver Percival's "Chats" is indeed the most comprehensive and

Hosted by Google

the most thoroughgoing work, in a single volume, on "old" jewelry and trinketry known to me. In the briefest terms, after a general review of ancient and mediæval jewelry, he writes fully, through just 400 pages, on every denomination, and every style, of modern "old" jewelry and trinketry; all further defined and exemplified by over 200 illustrations reproduced on separate plates from photographs, and over 70 sketches, in outline, embodied in the text, a total of some 300 illustrations. In this way the volume is found to be a truly exhaustive encyclopædia of modern jewelry, from the Renaissance to the days of our picturesque grandmothers—dating them in their feathers, and falling ruffs [fallals], and fluttering furbelows, and sheen of famous trinketries, back to the days of Edward Pinchbeck and his son Christopher. With other Oriental jewelry, Mr. MacIver Percival also treats concisely of the jewelry of India, which is everywhere, from Cashmere to Ceylon, and from Karachi to Calcutta, the jewelry of Chaldæa and Babylonia, and Assyria, and of Egypt, and of ancient Greece and Rome, surviving down to the present century as a still living art and craft,—except where it has been degraded and depraved in its art, and shamed, and dishonoured, and deteriorated, in its craft, by the sinister influences of our English Schools of Art, and our general system of English education enforced throughout the country. For the fulness of its illustrations of trinketry the volume is a most "thankful boon" to the student of the history of the applied arts, the historical painter, the working jeweler, and collectors, to the humblest "snapper up of unconsidered trifles"; and last, but not least, to the providential pawnbroker, and his necessitous clients. It is a veritable "Vade-Mecum" for the isolated working jewelers, and the trading jewelers, and the pawnbrokers scattered about in the Cathedral cities, and county towns of the United Kingdom. For the most part they have never yet grasped the fact that the true value of jewelry is in its patterning and colouring, and not in the weight of its precious metals and stones; and therefore, notwithstanding that a jewel may be of the highest artistic or antiquarian interest, if there is nothing in it for the melting-pot or the carat-scales, they despise it as "but a gaud" [in Scotland *gowd*], and "a trinket"; at once to their own loss, and of their patron; for at this moment better bargains in jewelry, so far as artistry is the consideration, are to be made by amateurs of taste and learning, out of the derelict stores of the pawnbrokers, of even such "knowing places" as Glasgow, Liverpool, Manchester, Birmingham, and London, than at any previous period within my own experiences. "Gaud" and "jewel" are one and the same word with the Latin "gaudium," "joy," the first coming to us directly from it, and the second through the Low Latin "gaudiellum," and Italian *gioiello*, a jewel; all going back to the Sanskrit *gauras*, "yellow," "shining," "bright," "cheerful," etc.; and again, although "trinket" and "trickery" are the same word [going back to the Sanskrit *tarka*, "twisted," "a spindle," "interlaced wire-work"], both are also the same word as "torque," the Asiatic gorget, one of which taken from the neck of the Gaul he slew in single combat earned for T. Manlius and his descendants the honorific surname of Torquatus. It is the same word as *trousseau*, originally the bride's "truss" or twisted bundle, of wedding garments and trinketry. I have always found these illuminating etymologies of great use in selling off jewelry sent by the Government of India to International Exhibitions in this country and in France.

A greater evil, because of national consequence, is the general ignorance of our working jewelers of the history of their own craft, even of the materials, and the chemical and mechanical processes, and of the very tools used in its manipulations; and this incredible ignorance, aggravated by the miserable neglect of all such knowledge by the mass of the shopkeepers "doing business" in the craft, is the immediate cause of this country having lost, during the first half of the nineteenth century, the proud place it once occupied among the nations of the Western World for its gold and silver wares, and its jewelry, and its trinketry; and also its exquisite passementery, for it may be held to lie within the borders of trinketry. They know little, and oftener nothing, of what has been done before them, and by our very selves, in their most ancient art and trade, and triumphantly done,—"for [as both Shelley and Isaiah xl. 15, say] an eternal excellency, and a joy for ever." They are ignorant not only of the pre-eminent kimelionic exemplars of other ages and other countries, but of their own country and age. It is not for a moment meant that they should slavishly and mechanically copy the designs and imitate the styles of such masterpieces of their glorious craft; but they ought all to be more or less intimately familiar with them; and for the ever-quickening inspiration of their hearts, and minds, and souls in their individual handiwork:—"The flame of the fire will scorch his flesh; but in the midst of its glowing heat he will wrestle with his work; and the ring of his hammer on it will be heard all the day long; for his eyes are set on the goodly shape of the vessel in his hands, and his heart is set upon the patterning over it, to adorn his work perfectly." * It was in this spirit that the art-craftsman of ancient Greece, while resting at noonday from his labours, meditating on the wonderful world around him, and above him, came to call its

* As at Ephesus of old, everywhere in India, through all the sunny hours, is heard the ringing note of the coppersmith's hammer; and around the rural villages, from out the scattered groves, comes the answering note,—*tonk, tonk, tonk*,—of the little, verdigris green barbet, or "Coppersmith" of Anglo-Indians; and this antiphony between the men in the bazaars and the birds in the trees fills the whole brightness of the firmament above, as with praise "to the Holiest in the highest." So long as it lasts, one would fain listen to it; spellbound in profounder enchantment than of—

> "The olive grove of Academe,
> . . . . . . where the Attic bird
> Trills her sweet warbled note the summer long."

Hosted by Google

Almighty Creator, "The Poet" [Ποιητής]. It is under the promptings of such divine inspirations that the handicraftsmen of India still daily, in the bazaars of a million cities and towns, and villages, heap up their jewelry of every denomination, in gold and silver, and precious stones [and not only for their women, but for their men, and children, and their pack-bullocks, and sacred cows, and horses, and elephants, and camels], as of the rich and rare spoil of Midian by Gideon, and of Seir by Jehoshaphat, and of the Persians at Platæa by the Greeks. When, on the "Cotton-crash" in Bombay, following the defeat of Lee, April 1st, 1865, at Five Creeks, I was asked to revalue a store of Indian Jewelry on which a loan had been advanced by one of the banks, the sight of it was as if I had suddenly come upon Hezekiah's own hoard of "exceeding much riches," in silver, and gold, and precious stones, and "all manner of jewelry," all of the antique models of a world that had come to a dead end in Europe 1,036 years before, almost to the very day! To the passing prostration of this mental, and moral, and religious stimulus between 1800 and 1851, is to be attributed the decay observable in most of the artistic industries of the United Kingdom within that period; and great as has since been the distinction achieved in every department of our textile and fictile manufactures, and in our domestic and ecclesiastical furnitures, and in metal work, including gold and silver work, all following on "the Gothic Revival" in Architecture, and notwithstanding what has been done in the present generation by individual goldsmiths, the revival has never yet manifested itself as of any national magnitude in our jewelry, sumptuary or democratic; and our "old" jewelry and trinketry remains, for the more fastidious of us, still "the only wear." The pre-eminent praise of Mr. MacIver Percival's book, emphasised by every page of it, is in its providing that inspiration; and by the simple means of handing down the historical, technical and artistic traditions of the beautiful objects he describes in so simple a form and so clear a manner as to render them understandable, and readily assimilable, by everyone, however imperfectly instructed, trained, and educated, and practically engaged, whether as working jewelers, or as business men, in the art and craft of "Old Jewellery and Trinkets." This is a matter of some moment; for the future of art is not with "the New Art" [l'Art nouveau], and "the Post-Impressionists" and "Futurists," but with the traditionists; and it is a future of unbounded hope and prosperity for all concerned with the decorative arts, and especially with jewelry and trinketry; and here is a book, a meet helpmate for them, wherein—"The very marrow of tradition's shewn," and so truthfully, so lucidly, and so invitingly, that "he may run that readeth."

The sum of the matter is this: in jewelry, as in every other creative work, tradition has to be observed and followed—or, at the end of a long life, the greatest jeweler will, at his best, but have arrived at the point from which he might have started, that is, the point of excellency attained by his professional predecessors; that the decorative details, and so far as possible the construction (where there is any construction other than what is provided by the details) are not to be arbitrarily dictated by the jewelry of foreign countries, ancient or modern, but by the living flora and fauna of his own country, and its national and local legends and heroical history, and antecedent artistic achievements; and that, this nowithstanding, any special power he may possess of giving artistic expression to these flower and animal fórms, and these spiritual inspirations, must still be exercised under the discipline of the traditions of his immemorial art and craft. Be assured no road to any heaven is easy:—

"Non est ad astra mollis a terris via."

None of the jeweler's individuality, if he has any, will be enfeebled by this severe discipline, it will be strengthened, and assert itself at its best; and while he will prize his design all the more for the flower that suggested it, he will thereafter love that flower all the more reverently for the consummate design he draughted from it. It was thus I witnessed the worship of the leaves of the "Indian Fig Tree" [*Ficus religiosa*], and of the silver "Fig-leaf" devised from them, for the wear, as their only vesture, and the earliest clothing of mankind according to the Biblical legend of Adam and Eve, worn by the wild Thakurs and Katharis of Western India; specimens of which were contributed by me to the International [London Annual] Exhibition of 1871, and described in my "Industrial Arts of India." The poorer women wore the natural leaf, the wealthier—as their reserved capital—the silvern leaf, fashioned to the exact heart shape of the natural leaf, but with its venation beaten out into the similitude of the *pipul* [compare our "Poplar," "populace," and "people"] itself, as "The Tree of Life"; a most scientific as well as most artistic convention; and although this silvern "Fig-leaf" is not the oldest actual jewel known to the world, in origin it is obviously the oldest ever fashioned by man.

A parting, well-earned word of praise is due to the printers and publishers for their part in the production of the book. In the colour and texture of the paper, the character of the types used, the legibility of the printing, and in the strength of the stitching and general "forwarding," it is everything that could be desired. But books on the artistic industries should be bound in the light blue of the eyes of Pallas Athene, and not, as in this case, in the dark, amethystine, or indigo blue of Hermes, the patron of mechanical industries, and artificers, rather than of arts-craftsmen and artists. But this is pardonable. The unpardonable solecism is that harsh daub of crude indigo along the top edges of the leaves of an otherwise accurately symbolical, and harmonious and firmly framed "format."

EXAMINATIONS COMMITTEE.

A meeting of the Examinations Committee was held on Friday afternoon, July 26th. Present:—Lord Sanderson, G.C.B., K.C.M.G. (Chairman of the Council), Sir William de W. Abney, K.C.B., D.C.L., D.Sc., F.R.S., Alan S. Cole, C.B., William Henry Davison, M.A., B. S. Gott, M.A., Dr. William Garnett, Sir John Cameron Lamb, C.B., C.M.G., Sir Philip Magnus, M.P., Hon. Richard Clere Parsons, M.A., Professor John Millar Thomson, LL.D., F.R.S., with G. K. Menzies, M.A. (Assistant Secretary of the Society).

"OWEN JONES" PRIZES FOR INDUSTRIAL DESIGN.

This competition was instituted in 1878 by the Council of the Royal Society of Arts, as trustees of the sum of £400, presented to them by the Committee of the Owen Jones Memorial Fund, being the balance of subscriptions to that fund, upon condition of their spending the interest thereof in prizes to "Students of the Schools of Art who, in annual competition, produce the best designs for Household Furniture, Carpets, Wall-papers and Hangings, Damask, Chintzes, etc., regulated by the principles laid down by Owen Jones." The prizes are awarded annually on the Report of the Examiners in the National Competition of the Board of Education.

Six prizes were offered for competition in the present year, each prize consisting of a bound copy of "The Leading Principles in Composition of Ornament of Every Period," from the "Grammar of Ornament," by Owen Jones, and the Society's Bronze Medal.

The following is a list of the successful candidates:—

Barlow, Albert E., School of Art, Salford, for a Design for Overmantel in Lustre Tiles.

Hosted by Google

Billington, Frank, School of Art, Macclesfield, for a Design for a Woven Tapestry Hanging.

Faulkner, Howard B., School of Art, Dudley, for a Design for a Stencilled Hanging.

Grimshaw, Walter S., School of Art, Accrington, for Designs for Printed Cotton Dress Fabrics.

Timmins, Marion L., School of Art, Dudley, for a Design for a Stencilled Hanging.

Woodall, Bertram, School of Art, Dudley, for a Design for Chintz.

The Examiners who judged the works submitted for this competition report:—

"490 works were submitted for this competition, and the general level of merit shown last year has been maintained. As was the case last year, the best examples are the Woven, Printed, and Stencilled Fabrics. Some good Damask and fairly good Carpets, Embroidery, and Laces were also submitted."

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

THE MATERIALS AND METHODS OF DECORATIVE PAINTING.

By Noel Heaton, B.Sc., F.C.S.

Lecture I.—Delivered March 18th, 1912.

The Development of Decorative Painting.

My first duty in addressing you is to define what I mean by Decorative Painting, and to indicate the lines on which I propose to deal with the subject.

The term "painting" is a very wide one, including as it does on the one hand the work of the humble artisan who "beautifies" our doors and windows at so much an hour, and on the other extreme the work of the inspired artist who achieves undying fame by the execution of those pictures which grace the walls of our public and private buildings. Between these two extremes there lies a class of painting which is a work of art but not an end in itself, fulfilling, as it does, the definite function of completing and glorifying the building of which it forms an integral part; and that is what I understand by decorative painting.

Although I have placed it thus in an intermediate position, a great painting of this kind is, to my thinking, the highest possible achievement of the artist, because here he must work under restraint and limitations, at the same time expressing his own ideals and co-operating with the general scheme of the building his work is to complete. He must deny himself the freedom of the picture painter, and rise superior to, without ignoring, his limitations.

I think Hamerton has truly summed up the subtle difference between the picture and the decorative painting in his epigrammatic statement that a picture no more becomes a mural painting by being glued to a wall than a man becomes a statesman merely by reason of the fact that he has been elected a member of Parliament.*

Any discussion of the question of design is, however, beyond the scope of my appeal to you. My purpose is to emphasise the fact that not only is decorative painting the culmination of the work of the artist, it is also the culmination of the work of the craftsman; it demands equally the highest genius of the one and the highest skill and knowledge of the other. This being the case, I maintain that the study of his materials and methods is an essential and vital feature of the work of the decorative painter. I do not wish to suggest that the decorative artist, if I may use such a clumsy term, should be a scientist, but I do say, and say it most emphatically, that he should realise the necessity for this knowledge—this co-operation, we might almost call it, of art and science; for ignorance of the technical principles on which the execution of such work depends has been disastrous in the past and will be still more disastrous in the future. To put it on the most selfish grounds, one cannot expect patrons to encourage the execution of decorative paintings unless there is a reasonable expectation of the necessary outlay being justified by the future history of the work. Many lamentable cases of failure have come under my own observation—expensive works which have perished or seriously decayed in a few years, such decay nine times out of ten being due to defects in the process or materials employed—disasters which could have been avoided by a little technical knowledge, or by seeking efficient scientific advice at the time of execution.

The task I have set myself in these lectures, therefore, is to try to point out to such of you as may agree with me as to the importance of this aspect of the subject, the principles underlying the processes you employ in painting, the pitfalls by which your work is surrounded, and to give you such assistance as lies in my power to enable you to execute paintings which come within reasonable distance of realising that somewhat

* "The Graphic Arts," p. 164.

Hosted by Google

optimistic saying that "a thing of beauty is a joy for ever." To this end I propose to devote this evening to passing in review the various methods of painting available; and in order to render this discussion of ways and means as interesting as possible I propose first of all to inquire, as a matter of history, how the various methods of painting now available came into existence.

We must go right back to Neolithic times to trace to its source the craft of decorative painting, for it is obviously the mother of all painting, and came into being as soon as primitive man developed the instinct to decorate the walls of his rude dwelling with signs and pictures. The natural beginning in all parts of the world was for the savage to gather such coloured substances as he could find around him, make them into a paste with some sticky liquid, and so spread them over any surface he desired to colour. Black, yellow, red and white are the colours one invariably finds in primitive paintings. Charcoal black obtained from the ashes of the fire, yellow from clay stained with iron, which we call ochre, red obtained by calcining the same yellow, whilst chalk or powdered limestone produced an excellent white; all these mineral pigments, or earth colours as we term them, are obtainable all over the world.

From such crude beginnings arose the decorative art of Egypt, which had developed to a highly advanced state as early as 4700 B.C., as is evident from the fragment of wall painting I now show you, representing a man holding a leopard by the tail, and executed in the reign of Sneferu. On examination of a section of this painting, it is evident that it was executed in the following manner: the rough surface of the mud wall was first of all levelled by a liberal coating of rough plaster, composed of Nile mud and chopped straw, which was followed by a thinner coat of finer texture, composed of powdered gypsum and very finely chopped straw. On this again the final smooth surface for painting was produced by a thin coat (about a sixteenth of an inch in thickness) of pure finely-ground gypsum. This plaster was allowed to dry, and then painted with such pigments as were available, the binding material being a solution of glue or size.

Although the naturalistic treatment of design shown in this example disappeared from Egyptian art for many centuries, being succeeded by a more formal and conventional treatment, this distemper process, as we might term it, remained at all times their method of painting, and we find it still in use in 1400 B.C., when the heretic king Akenhaten reintroduced for a time the naturalistic treatment, as evidenced by the paintings of the Palace at Tel-el-Amarna.

[Slides were here shown of examples of Egyptian mural paintings of different periods from the Third to the Eighteenth Dynasty.]

I have referred to these early paintings more particularly to emphasise the fact that you must not judge the durability of a painting by the evidence of ancient examples without reference to the situation in which they were placed. Although these examples have come down to us in a very fair state of preservation, they would not last for five minutes in this country unless placed under cover, for they will not resist the touch of a damp finger. Such a method of decorative painting is, in fact, only possible, except for the most temporary purposes, in a practically rainless country like Egypt, and in other contemporary countries where circumstances were not so favourable, we find that paintings executed in this manner have only survived in small fragments, and that they are largely replaced by sculptured stone, glazed brick, and so on.

But during the last ten years it has come to light that whilst those things were being done in the East there was arising that great Minoan Empire which dominated the Mediterranean Sea during the Bronze Age, and which had its centre in the island of Crete. Now, the climate of Crete is not like the climate of Egypt; it is more like that of our own island, and consequently we find developed there a more durable method of painting which the Egyptians apparently never thought of, because there was no reason why they should seek for anything better than distemper.

At least as early as the year 3000 B.C. the Minoan builders discovered that by merely mixing a pigment with water and spreading it over the freshly prepared surface of lime plaster they could colour that surface in a manner that was remarkably durable when exposed to weather. It would be beyond the scope of these lectures to describe in detail how the method of painting we call "fresco" was evolved from this beginning. It will suffice to indicate the method of working in the palmy days of the Minoan Empire, when civilisation was at its highest, and there flourished at the capital Knossos and elsewhere a great school of decorative painters, who from long tradition had developed a skill in this art which, to my thinking, has never been surpassed.

The wall was, if necessary, first rendered to a

Hosted by Google

fair surface with rough plaster composed of lime mixed with an aggregate of pebbles and fragments of pottery, etc. On this was laid a first coat of fine plaster about half an inch thick, composed of pure lime, and on this again was laid the finishing coat, a quarter of an inch thick, to receive the painting, which was executed whilst the plaster was still wet, the pigments being merely mixed with water and laid on with a brush, and the work being executed with a rapidity and certainty born of established tradition and long practice.*

This was a necessity, because whatever was attempted must be finished without loss of time, for in fresco painting, as soon as the plaster is laid down the process of setting commences, which renders it insoluble, and, in doing so, binds the pigments firmly to the surface, a point which I shall discuss in detail in my next lecture.

Before I go any further I must remind you that the term fresco painting is frequently used at the present time in a generic sense, to imply *any* painting on a wall or building, however executed. I propose, however, to limit it strictly to a painting executed in the manner I have just roughly outlined, that being the original connotation of the word. This method of decorative painting has certain qualities which can scarcely be attained by any other method; qualities derived partly from the severe limitations it imposes upon the artist, and partly from the nature of the surface and the entire absence of anything in the way of a vehicle or medium, which is required in all other methods of painting in order to attach the pigments to the surface.

I have indicated that the Minoan artists developed this process to a high state of perfection; it was the art of the period, and every available space on their buildings—walls, ceilings, and even floors and stairtreads—were decorated in this manner.

The headquarters of this craft were at Knossos, the capital of the Empire, and there is reason for believing that not only did the artists execute work *in situ* in the great city itself, but that they made up the plaster in loose panels and exported finished paintings to other cities, to be built into the walls. I show you, for example, an illustration of a fresco discovered in the island of Melos, which was evidently exported in this way.

* For a more complete account of the technology of Minoan painting, see "Minoan Lime Plaster and Fresco Painting," *R.I.B.A. Journal*, September 30th, 1911.

With the overthrow of the Kingdom of King Minos, and the transfer of supremacy to the mainland of Greece, which occurred about the year 1400 B.C., we find the fresco painters flocking to Mycenæ and Tiryns, and continuing the practice of their craft, although in a less masterly fashion. The palace of Tiryns, originally excavated by Schliemann many years ago, has recently been re-excavated by the German Archæological School at Athens, and many fragments of fresco discovered, sufficient to enable a reconstruction of some of the original designs to be made, which work was only completed this year. I have the privilege of showing you photographs of these restored designs, which are of most remarkable interest.

[A number of autochrome reproductions of the frescoes referred to were here thrown on the screen.]

If you compare these designs, however, with those of Knossos, you will see that there are distinct signs of decadence, which is still more marked in the well-known figure of the bull, discovered at Tiryns by Schliemann. This marks the last stage of an art dying for lack of patronage, which appears to have come to a standstill altogether with the Dorian invasion.

The revival of the art in classical Greece was developed on different lines, sculpture becoming the established method of expression, and although decorative painting was pursued to a certain extent during this period our knowledge of it is very vague. We read, for instance, of the wonderful paintings executed by Polygnotus at Delphi; but, unfortunately, when Delphi was excavated by the British School at Athens recently no trace of these paintings was discovered to enable one to judge of the method of execution. But from the fact of their disappearance and other evidence which it would be outside our present purpose to discuss, it seems probable that during this period statuary was coloured and mural paintings executed in a manner similar to the Egyptian distemper painting, only with an improved medium prepared from yolk of egg, a process of painting known to us as "Tempera." In Egypt, during the Ptolemaic period, for instance, we find paintings executed in tempera by Greek artists, as an example of which I may refer to the remarkable series of coffin portraits discovered at Hawara by Professor Petrie, and exhibited recently at University College, when I had the opportunity of preparing the autochrome photographs of the best examples, which I shall now

Hosted by Google

throw on the screen.* The earliest of these were painted in tempera on canvas, primed with a mixture of chalk and wax, which was laid over the canvas to form a thin coating like gesso. The later portraits on the coffins from the same cemetery, however, were executed in an entirely different manner, being painted on thin panels of cedar by the method we know as "encaustic," in which the medium consists of wax, which was melted and mixed with the pigments.

We thus find that by the dawn of the Christian Era, at least three methods of painting of a more or less permanent character were available, leaving out of account the soluble distemper of the early Egyptians; and it is probable that these three methods were employed side by side by the later Romans, who revived in a modified form the fresco process of the Minoans and used it extensively, in addition to tempera and encaustic. The Roman plaster was much thinner, the first coat being composed of lime and small pebbles, and the final coat, which was barely one-tenth of an inch in thickness, of lime and marble dust; a more extensive palette of pigments was employed in the painting, such substances as terreverte and red lead being used, in addition to the few pigments of the Minoans.

The method of painting in Roman times can be best studied at Pompeii, where we find unmistakable evidence that in addition to fresco, tempera and encaustic were also largely used —more particularly we find a modification of the latter, in which the painting was executed in distemper and then rendered durable by impregnation with molten wax— an easier method of execution than that of actually painting with the wax medium.

Fresco was very largely employed in this country for the decoration of houses in Roman times, as is evident from a study of the remains of many cities and detached villas which have been excavated. With the break-up of the Roman Empire there was another period of decline, followed in mediæval times by the rise of mosaic and then stained glass as typical methods of decoration. Decorative painting was, however, very widely practised throughout the Gothic period, as is evident from the many remains existing in our churches—such as these at Southleigh, Oxfordshire, which I now show you, these paintings being for the most part roughly executed in tempera.

* A "Portfolio of Hawara Portraits," containing facsimile reproductions of these portraits, will be published shortly by the Egypt Exploration Fund, University College, W.C.

With the dawn of the Renaissance of art and learning in Italy, decorative painting came into greater prominence, and, as we can gather from the many treatises written on the art, great attention was paid to the study of materials and the elaboration of the various processes. Encaustic painting does not appear to have been utilised to any extent, but tempera and fresco were widely practised. The latter was reintroduced about the close of the fourteenth century, and the problems surrounding it were deeply investigated, as we can tell from the well-known writings of Cennino-Cennini; many of the mediæval workers in fresco, such as Pinturicchio, frequently attempted greater elaboration than the method rendered feasible, and had recourse to after painting in tempera to complete their designs. The range of substances used as pigments was also greatly enlarged by continual experiments; and although amongst them many of doubtful durability were included, the painters, as a rule, were so familiar with their nature and properties as to be able to select their palette to ensure the best effect with the maximum durability.

Time does not permit me, however, to dwell at length upon the methods of the mediæval painters, which have been ably discussed on previous occasions; but, as their technical and manipulative skill increased we find that a new spirit began to spread over painting. There was a growing tendency to elaboration and subtlety of design, a striving for clearness of expression and realisation of natural detail which led to the seeking for a more facile medium, without the severe restrictions of tempera and fresco, a tendency which called forth the rebuke of Vasari, "Let all those who wish to paint upon walls paint in fresco like men, without retouching in secco, which, besides being a most vile practice, shortens the duration of the pictures."

Towards the end of the fifteenth century there came that utter revolution of the method of painting heralded by Alberti in his treatise, at the close of which he makes the remark: "It has been recently discovered that all colours can be mixed with linseed oil, and will last for ever, provided that the wall upon which they are put be very dry and completely free from damp."

The idea that the Van Eycks were the first to realise the peculiar property possessed by linseed oil of "drying," as it is termed, is, of course, long since exploded: we know perfectly well that drying oils had been in use for the humbler purposes of house decoration for generations

Hosted by Google

before their time. But there is much to be said for the idea that they were the first to employ linseed oil, not alone, but in combination with resin, to ensure greater facility of execution. The secret of the method by which they produced their wonderful works perished with them, and it is impossible to identify it with certainty. It certainly was not known to their successors, who endeavoured, without success, to imitate them by using linseed oil—at first sparingly and then more freely—until they abandoned everything else and used linseed oil *alone* as their vehicle.

It is easy to understand that once this point was arrived at, the earlier methods of painting were soon entirely abandoned in favour of such a facile medium, which is the servant and not the master of the painter, allowing him to work out his composition as he goes on, and alter and repaint as much as he likes, instead of having to think it all out beforehand and execute his work with certainty and without pause.

This freedom from restrictions fostered the growing tendency towards the production of works of pictorial rather than decorative art, which, together with the demand for work of a portable character, gradually led to the abandonment of decoration in favour of pictorial art, and finally resulted in our own times in such a complete elimination of the earlier methods, that to the average man of to-day the word artist is almost synonymous with a painter of pictures in oils.

The distinction between a picture fixed on a wall and a wall painting has been largely lost sight of, both as regards design and method of execution, and huge pictures take the place of decorative paintings. But, apart from the fact that the limitations of technique and design imposed by these earlier methods of working are by no means an unmixed evil, as tending to simplicity and vigour, we find that an ordinary oil painting, for several reasons, is by no means satisfactory as a permanent work of decoration.

This fact has been generally recognised in recent years, and many experiments have been made in the modification of the process of painting, and also in the revival of ancient methods of working, experiments which have, however, frequently been a disastrous failure through ignorance of the scientific principles involved.

For, in executing work of this character to-day, and deciding upon the method of execution to adopt, we must frankly face the fact that conditions have changed, and that in many ways the problems that surround us are infinitely greater than they were in ancient or mediæval times.

We must face the fact that we have to contend with the impure atmosphere of our cities, contaminated with the products of combustion of coal, and the inevitable impurity that results from the massing together of enormous numbers, together with the concomitant evil of smoke and dirt, which necessitate paintings being so finished as to be readily cleaned. We have to face, moreover, the economic conditions dependent upon our modern civilisation; the fact that everything must be done in a hurry, and that in many cases the execution of a painting *in situ* is rendered impossible.

It is of no use ignoring these limitations; they are the penalties of modern life, and they must be grappled with and conquered. But there is no denying that they render all the more imperative a thorough understanding of his materials by the artist; in fact, the more experience one gathers the more one is forced to the conclusion that the production of a permanent work of decoration under modern conditions, is one of the most difficult problems of applied chemistry.

In order to resist decay efficiently the surface of the painting should be hard, elastic, and polished like a mirror—such a surface as the coach-painter produces on his panels by successive coats of varnish made of the hardest resins, each coat smoothed and brought to a dead surface before the next is applied. But such a smooth, glossy surface would be anathema in a decorative painting; what we seek for is a matt surface, so that the work can be seen in any light, and the brilliancy that can only be obtained by such a surface as that of plaster; such a surface in fact, as one knows from experience, is least calculated to resist decay, affording, as it does, foothold for every kind of dirt, and inviting the attacks of every kind of impurity.

In deciding upon the method of working, our problem is, therefore, to find a compromise between these two conflicting conditions; to obtain the maximum amount of durability with the necessary æsthetic quality.

Of course we must realise that no method is perfect; neither is there any method of painting which can be pronounced satisfactory under all conditions. At the best it is a fight with circumstances, but much may be done to defy the ravages of time by fully realising the defects and limitations of the various methods available, and by modifying them in order to secure the best results under different conditions.

BRITISH FISHERIES.*

The Government in this country until very recently have paid very little regard to fishing. The first attempt of any kind of official organisation or control was by the Scotch, or it was the Scotch Fishery Board, and I should imagine myself that action points to the fact that the Scotch herring fishery is of much earlier date. It was fostered officially and watched over long before it was in England. The branded herring, of course, became the commodity of traffic, and when we commenced we sold to many nations large quantities of herrings. Then again one is reminded that the herring fishery is a very ancient institution, for the barrel of herrings, I dare say you will find in your reading, was looked upon as a measure of exchange. The value of a barrel of herrings was often quoted as a standard of value in commerce.

Size of the Industry.

With regard to the magnitude of the fisheries of Great Britain, in point of number of vessels we have gone down, but in point of value and in catch we have gone up. There appear to be, from the last Board of Trade returns, 24,459 fishing vessels of all classes in this country, and they landed, in the last year I have any record of, 1,133,711 tons of fish, so we have certainly provided food for the people. The value of that fish seems to be about 11½ millions sterling, and the value of the fishing fleet seems to be from 22 to 23 millions sterling. Now, going into detail as to where that value lies, in what branch of the industry, and what part of the country, you will find that we in this part occupy a very important position. The east coast, with which we are connected—Hull, Grimsby and the northern ports on the east coast—has provided nearly half of the whole fish landed, rather more than half a million tons, and the value of it is set out at £6,292,936. That is the east coast only. The south coast only contributed about 33,000 tons, valued at less than half a million of money, and the west coast contributed about 64,000 tons, being about one million in value. The whole of Scotland contributed rather less than half a million tons, and the value of it was two and a half millions. That is a summary of the value of our fishing trade. As to the vessels which you, with your mechanical and technical knowledge, have helped to foster, and have under your charge very largely—there appears to be £8,234,000 worth of property in what we call the deep-sea fisheries in Great Britain, and the value of the property in the herring fishery is £1,483,000.

Influence of Steam.

Now the steam herring boats are quite modern, as you know. Dealing with the fishing as a whole, of the 22 millions sterling it appears that steam vessels account for £11,687,000 and the small craft, trawlers and other description of fishing vessels, works out at another 11 millions. If you take your minds back only twenty-two years—when steam was first introduced generally, although it had been to a small extent in existence before that—in that period we have added to our value in that particular class of vessel half of the value of the fisheries of Great Britain. There appear to be 2,790 steam vessels in Great Britain, and of other craft over 20,000, making up 24,459, so that during the last twenty years we have been largely dependent on the skill of you gentlemen. In fact, by the technical knowledge of the engineer, combined with the practical knowledge of those who have embarked in the industry, we have produced a machine for catching fish such as never existed before. The steam trawler seems to be the envy of the world. Every part of the world where they now embark in fishing comes to Great Britain for the steam trawler, and notwithstanding the early development of other branches of the fishing industry we still hold the field; we claim our rights and say as trawling people we play an important part in the nation, and that we supply a very large moiety of the food of the people.

Figures from other Countries.

In order to compare this country with other nations, which were in the field before us, I have obtained some figures. There are Holland, Belgium, Denmark, Portugal, Russia, France, Canada, and the United States. I have not the details of the various ports, but so far as France is concerned they have, it is stated, 27,848 fishing vessels, and they employ 153,339 people, whilst the value of their fishery is £5,677,608. Now Holland, a nation of which I have spoken, have only 5,350 vessels, and 20,000 fishermen, and the value of their fisheries is a little over three-quarters of a million. Belgium appears to have only 460 fishing vessels, and the value of their fisheries is £250,000. Norway, another seafaring nation, appears to have 24,260 fishing boats, and 85,000 people employed, and the value of their fisheries is about 2½ millions. For Denmark I have not the number of the boats, nor the number of persons engaged, but their fisheries are supposed to be worth rather more than three-quarters of a million. The fisheries of Portugal, I was surprised to see, are valued at a little more than one million sterling. For Canada, our own colony, I have not the number of the boats, nor the number of men, but the value of their fisheries is said to be £5,240,000. Neither have I the details for the United States, but their value—and I take this to be the shore and not the lake fisheries—is just about half the value of the fisheries of Great Britain.

Is there any Depletion?

There is not the slightest doubt from everything I find recorded, and from my own observations, that the North Sea is one of the most wonderful fishing grounds in the world. It certainly provides

* Extracted from a lecture on "The Development of the British Fisheries during the Nineteenth Century," delivered by Mr. G. L. Alward, J.P., before the Grimsby Institute of Engineers and Shipbuilders.

Hosted by Google

some of the most delicious fish, and a great variety, and it appears to be almost inexhaustible. Twenty odd years ago we thought we had got to the end of our tether. I remember a day in November of 1886. We opened an association to get an exchange of opinion amongst the fishing people of Grimsby as to whether something very serious had not happened, whether the trade had not come to an end, whether we had not exhausted the North Sea, and what was to be done for the future. Well, we have profited by experience, and we have had to let go the theories we held. But what has happened is this, that the Governments of this country, and of other European Powers, were roused to the fact that they ought to know more about the fishing industry, and so we had the International Sea Fisheries Exhibition held in 1882, which brought together the fishing instruments, the implements and the craft from all parts of the world, and we had an opportunity of seeing what was being done by the Americans, and by all the European Powers. I have already stated that we in Grimsby were to the front. We produced our ship, we competed against them all, we got our prize, and from that day onwards the Government of this country, and the Governments of the other countries of Europe, have been alive to the value of our great fisheries. But it was not until some time after that statistics were taken at all. We had our surmises as to whether there was more or less fish in some parts of the sea, and as to whether it was a permanent diminution, or only a temporary one. But now we have had scientific investigation, and I have previously tried to explain what is the outcome of that. We have now got a grip of the fisheries, and know much more than we did twenty-five years ago. As I have said, the North Sea is perhaps one of the most wonderful fishing grounds in the world. It covers 46,000 square miles. We still go fishing on the same old grounds, sometimes with good, sometimes with bad results. Then with these wonderful craft in which you are interested, we have gone further afield, and to-day we are fishing over an area of 170,000 square miles of fishing ground. So you see that, pessimistic as we were at one time, we are still going on. Whether we shall ever arrive at the climax I do not know.

"The Last Sole."

In going over these items I thought it very wonderful that in one's lifetime it should have been possible for one to have gone to sea in craft 35 ft. long and about as wide, fishing a few miles from the shore, thinking then we had got to the end of our tether, and then to see the result before us to-day. I remember an old fisherman at Scarborough, perhaps it was only a byword, of whom it was said he had been toiling hard for a long time catching soles, and he brought one pair ashore, and he held them up, and said: "The last pair of soles in the sea." We have not caught the last soles, we have not caught the last plaice. There is something very peculiar about fish, and the scientific investigation has revealed something we did not dream of. The Government now know something about fish, and there is no doubt we shall receive great benefit from that. But I was going to remind you that the area over which we are fishing now with craft belonging to Great Britain and other nations, extends from 30 degrees north to 70 degrees north, being a range of 2,460 miles north and south, with a longitude from 30 degrees west to 45 degrees east, a range of 2,250 miles. That is the area which I have already stated. That confirms what I have said about our fishing industry, that it is one of the most marvellous industries there is in the world, and I must say that Great Britain has to its credit some of the exploration of these distant waters. It is perfectly true that the French went to Iceland years before we did with their cod vessels, and it is true that the Dutch fished for the herring on the Dogger Bank before we did, but I have spoken of the Thames fishermen, and it is to the credit of Harwich, which had a considerable number of vessels in the seventeenth century, that they frequented the North Sea for line fishing, and it was at Harwich they adopted the Dutch system of building the vessels with wells in them in order to bring the fish alive to the market.

Ports that are Dead.

Harwich, as a fishing town, has died out comparatively. Barking, which was an industrious town, and had a large fishing fleet, has ceased to exist as a fishing town. Gravesend, for deep sea purposes, has ceased to exist as a fishing port, and one or two other ports have disappeared. I perhaps ought now to address myself a little more closely to what I mentioned before, that is, as to why some ports have died out, and why others have grown. The principal reasons in days gone by for fishermen locating themselves at some particular port were two. One was the nearness of the fishing ground, and the other was to be near the centres of population for the distribution of the fish caught. The old Brixham people, and also the fishermen of Plymouth, frequently caught the hake at certain seasons, a beautiful fish, but they had no possibility of placing it amongst the centres of population. They came up to Portsmouth with some of their fast little craft, one boat taking the cargoes of two or three, and reaching Portsmouth on the following day if possible. Large cargoes were also sent off for Billingsgate, but if the wind faltered they had to throw the cargo overboard and go back again. That was considered a crying shame, and the member for Brixham, to his credit, when salt was dear on account of the tax, secured a special permission for Brixham fishermen to salt their hake free of duty, and that gave an impetus to these people, and enabled them to get a living instead of having to destroy a large quantity of fish. They came up Channel and pitched their tent at Dover. That was the first step, the trawlers thinking they would do better if they were nearer to the centres of population. At Dover they found two wonderful fishing grounds,

Hosted by Google

the Ridge and Varne, and round those banks, I have heard my father and others say, they got trawls full of beautiful turbots. The turbots came frequently but vanished again, sometimes not being found for a long time.

BIRTH OF HUMBER FISHERIES.

Then Ramsgate put in a plea, and the fishermen settled at Ramsgate. Some of the Grimsby people living to-day came from Ramsgate. I myself was born in Ramsgate. But there was no rest for the soles of their feet. They plied all the waters round the French and Dutch coast, working them for years. The more courageous of the fishermen came further north; they passed the River Humber, and located themselves at Scarborough. There they came into collision with the drifters. One man was thrown overboard, but his life was saved. This struggle developed, until the Government stepped in and said: "Hold your hand," and declared it was illegal to use a certain instrument which I shall show. In my time we had got as far as Scarborough. My first sea voyage was from the River Humber. We went further north, using Whitby, and the Tyne ports, and my father went, I believe in 1847, to Newcastle. I suppose they had never seen a trawl fish there in their lives before. And whilst we explored the waters along the shore we also went out further to sea.

THE FLEETING SYSTEM.

The Thames and the Devonshire fishermen, as they pushed further out to sea in the old days, were met with great difficulties as to getting their fish to market. With the variation of wind and weather they would not at times have a sufficient catch to bring to market, and eventually they had to resort to other means. One of the means adopted was the working together in companies at sea, sending their catch to port by one of the vessels, and in some instances sharing the spoil. Later, craft were specially built, which were faster sailers than the fishing boats, more like yachts, and these were called fish cutters, or carriers, and the owners at the famous port of Barking took the lead in this matter. The Hewitts and Morgans who were great fishing-vessel owners, built many of these special craft, and these same people introduced the idea of preserving the fish in ice. They pushed their operations far out into the North Sea, and on to the northern parts of the Dutch coast, and every day one of the cutters would take the fish from the fleet and convey it as quickly as possible to Billingsgate market. The Devonshire fishermen availed themselves of the opportunity of joining these fleets, and for years this was a prominent institution of fishing. The fish were packed first in baskets, sometimes in boxes. There was a charge for carrying, which in some cases was placed at one-fifth of the price made by the fish. This method called for continual improvement in the carriers, for increase in size, and when it reached its highest perfection a fleet of some twenty or thirty carriers plied through the waters all the year round. Of the energies put forward by the captains of these cutters many remarkable stories are told, such as a captain sticking to his helm from the time he left the fleet until he arrived at Billingsgate, often a thirty to forty hours' passage. This was carried on for some thirty years, the Devonshire fishermen who had come up coast adopting it, and in the early days fish was brought in these cutters either to London or to Grimsby and Hull. At length the distance became so great that steam power had to be adopted, and the Barking owners were the first to adopt it. About the year 1868 steam carriers were adopted, certainly of a somewhat rude character, but they answered the purpose well. Hull and Grimsby followed suit. Grimsby ceased the fleeting system some twenty years ago, but it was revived by one firm some twelve or fourteen years ago, though not for long. Now Grimsby has withdrawn entirely from fleeting, so that only Hull is left to follow that method, and Hull carries on one of the most permanently remunerative systems of deep sea fishing that is in existence.

ACCIDENTS ON INDIAN RAILWAYS.

Appendix XXII. of the Administration Report on Indian Railways for 1910 contains some figures of interest to manufacturers of railway rolling-stock, and to those responsible for its supervision and inspection before dispatch. Naturally this appendix takes account of collisions, derailments, floods, etc., but eight headings are given for accidents of rolling-stock due to failures of materials. Each class is further sub-divided into serious and other accidents. No deaths of passengers are attributable in either 1909 or 1910 to failures of materials, and only five cases of accidents to railway servants, of which three were fatal.

In 1910, the total number of accidents due to the bursting of boiler tubes was 257, as compared with 316 in 1909. There were, however, no fatalities due to these occurrences, only one man being injured in 1910. During these two years one boiler burst, but no one was either injured or killed on this occasion.

By far the most numerous accidents in both years were those due to the failures of engine springs and machinery, the figures given for these in the report being 892 in 1909, and 896 in 1910. No casualties of any sort arose from these accidents.

The next in numerical order are those accidents due to failure of couplings, the figures for these being given as 420 in 1909, and 435 in 1910, but again in no case was there any injury either to passengers or employees.

The failures of tyres, wheels, and axles, accounted for 76 accidents in 1909 and 52 in 1910, a decrease of about 68½ per cent. as compared with the preceding year.

On the other hand, accidents due to the failure of brake-gear rose from nine in 1909 to eleven in 1910, there being no casualties in 1909 and one in 1910. Accidents due to broken rails also rose from

Hosted by Google

214 in 1909 to 272 in the following year, this being an increase of nearly 27 per cent. in one year.

Accidents due to failure of materials, although numerically the least, yet causing the greatest loss of life, were those owing to the falling in of tunnels, bridges, viaducts, and similar structures, of which accidents there were two in 1909 and four in 1910, those in the latter year involving the loss of three lives.

Taking these accidents as a whole, it appears that those due to failure of rolling-stock, permanent way, etc., in short, to items of plant which receive careful inspection at the manufacturers' works, 1,929 in 1909 and 1,931 in 1910, were only responsible for three deaths and two injuries in the two years.

Considering the enormous mileage of railway in the whole of India, and the capital represented by this, these statistics reflect great credit upon those responsible for the specifications to which the various items were made, and upon manufacturers and inspectors for careful oversight of the material used.

ARTS AND CRAFTS.

Examinations in Art.—The circular recently issued by the Board of Education on Examinations in Art seems to be causing rather more than the usual flutter generally raised by such official documents in educational circles. It will be remembered that the Board put forward a sort of outline scheme of examinations at the end of last year. The present circular is meant to be read in conjunction with that, and it is this combination of the two which is responsible for part at least of the present difficulty. A large part of the new syllabus treats of Fine Art, and has not to be taken into account here. The portion which deals with Industrial Design comes at the end of the document, and seems to have been drawn up with the idea of being as vague as possible. There is, of course, a good deal to be said in favour of not making a syllabus on rigidly hard and fast lines, but one which, with slight modifications and a few alternative provisions, covers thirty-one different crafts, leaves, of necessity, so much to be guessed at or inferred that it is not to be wondered at that the teachers are feeling a trifle bewildered. Again, the crafts in which students may be examined are set out in lists, and letters are placed after them to indicate whether they are to be regarded as involving, respectively, modelling (M), a knowledge of architecture (A), and the use of the figure (F), or any two or all of these subjects. That, again, is a wise arrangement, but the way in which the letters are allotted makes it appear as though the syllabus had been drawn up by architects and painters rather than by designers and craftsmen. Why, for instance, should every embroidress, illuminator, and jeweller be forced to offer the figure? It would surely be enough to allow workers in these crafts to do so if they so desired. It seems at first sight more reasonable to expect a knowledge of architecture from the wall-paper designer, the wood-carver, the tapestry designer, and the glass-painter; but when we turn to the earlier scheme, we find that architecture includes the "drawing of the classical orders to scale from memory, and of a plan, section, and elevation of a building." This does not look as though the kind of architecture contemplated were peculiarly well adapted to the needs of the class of students who are to be examined. It is, of course, far easier to criticise a syllabus than to construct one, and the framers of this particular scheme had a well-nigh herculean task before them. They have tried to provide tests which will ensure that in the future the possession of a Board of Education certificate in Industrial Design shall indicate a certain amount of all-round education in art as well as proficiency in one particular craft. If they have not succeeded in doing this in the best possible manner, that is largely due to the fact that for the most part they were not directly associated with the crafts and industries in question. It is to be hoped that, so far as Industrial Design is concerned, the present circular may be regarded as merely a preliminary and temporary scheme, to be supplemented at a later date by a series of more detailed syllabuses which, if put forward by the Standing Committee of Advice for Education in Art, will be drawn up with the advice and assistance of the experts who will presumably be appointed as examiners in the various subjects.

French Textiles at the Victoria and Albert Museum. — The collection of French textiles generously lent to the Victoria and Albert Museum by the *Mobilier National*, which is to be on view in the North Court of the Museum until October, is important from several points of view. In the first place, the seven large Gobelins, after Raphael's famous frescoes in the *Stanze* at the Vatican, have never before been lent to any museum outside France. They are fine examples of an early period of Gobelins manufacture, and, incidentally, an object-lesson in what can and what cannot be successfully attempted in tapestry of their kind. The splendid scene, crowded with figures in armour and rich array, of the Expulsion of Heliodorus from the Temple, though it lacks to some of us the qualities of the earlier Flemish work, is quite unusually satisfactory. The woman in the handsome damask dress in the Parnassus catches the attention at once, while the School of Athens, with its groups of half-naked or soberly-clad philosophers, in spite of being one of the earliest pieces shown, is poor and cold in effect. The Savonnerie carpets—of the period of Louis XIV., and very fine examples of their kind—are interesting as products of the earliest renowned manufactory of pile carpets in France. Though tapestry carpets were fairly common at this time, the making of pile carpets after the Oriental manner seems to have been rare in Europe, except in Spain, where, owing probably to the close connection with the

Hosted by Google

East, they were produced at a much earlier date. The numerous velvets, brocades, and damasks which are shown in the various cases, form a very representative collection of the work of the Lyons weavers of the early nineteenth century—beautiful specimens of technique, often fine in colour, and with all the charm of really good silken fabrics. The embroideries as a whole are less interesting, but there is a small border with a renaissance pattern in gold thread, which is remarkable as being worked straight on to the velvet ground, Oriental fashion, instead of being applied. On the whole, one cannot help feeling that interesting and beautiful as these examples of French accomplishment and technical skill are, this is hardly an opportune moment for showing them. The English craftsmen of the modern school are bitten with the idea of simplicity at all costs, and the rather riotous design of the Savonnerie carpets, the set type of many of the patterns of the Empire silks, are the very last things to appeal to them. It seems, therefore, probable that many of those who might learn something from the masterly draughtsmanship and planning of some of these textiles, will see in them simply examples of a period with which (probably quite rightly) they are completely out of sympathy. The middleman, on the other hand, who is generally only too ready to receive with open arms anything to which he can attach the label of a French style, wants no encouragement to call for patterns which, whatever individual taste may think about their intrinsic merit, are undoubtedly better fitted to the genius of French than of English designers.

The School of Art Wood-carving.—The School of Art Wood-carving at South Kensington has been holding a rather informal little exhibition of the work done by the pupils taking the school's full course of instruction. There was no work executed for exhibition purposes, but a very interesting little collection of carving demonstrating what the first year, second year, and third year students have been doing during the year. It was schoolwork pure and simple, but it showed how well and thoroughly the pupils are trained, and quite accounted for the fact that the trade students find work at good wages when they leave the school, and that so many teachers of wood-carving all over the country have been trained there. A great deal of care seems to be taken to continue the education of the young students who are going to enter the trade on lines which have a bearing on their craft, whilst the drawings and designs on the walls, and the specimens of modelling scattered about the room, showed that the course is framed so as to give both them and the ordinary students something more than a knowledge of wood-carving technique. Casual students who join for a few lessons, of course, and the evening students, learn wood-carving only, but the regular pupils receive instruction also in the rudiments of those allied subjects which, indirectly at least, will help them so much in after-life. The school is remarkable not only for the work it does, but as an institution which teaches successfully both trade scholars and amateurs. Schools usually cater for the one type of students or the other, and both classes suffer a little from that fact.

The Allied Artists' Exhibition.—There is generally a small Arts and Crafts section at the Allied Artists' Exhibition at the Albert Hall, and this year was no exception to the rule. Besides a rather interesting stand of pots by Mr. Tunnicliffe, a satinwood grand piano, decorated in beaten copperwork by Mrs. Stannus, and a few exhibits in embossed leather, there were quite a number of cases of jewellery. Some of these were very much overcrowded, and looked as though the exhibitors had scraped together everything they could find—good, bad, or indifferent—instead of trying to make a good show of their best productions. There was, too, a certain amount of work which was rather more showy than beautiful, but some of the craftsmen sent exhibits worthy of better company. Miss Edith Linnell's chains and brooches showed a great taste and ingenuity in the manipulation of simple problems of design. They were the kind of things one would be glad to possess, and could live with without growing weary of them. Miss Florence M. Rimington sent some well-made and carefully-designed silverwork, clasps, etc., and Miss Ethel Virtue's little case included some work rather unlike what we usually see over here, and pleasantly reminiscent of some modern French jewellery.

CORRESPONDENCE.

A CERTAIN TUNIS POTTERY.

To find to-day, within thirty hours of Marseilles, the decoration of pottery of an archaic Greek type being actively carried on, would be astonishing did one not know the deep-rooted conservatism of the Oriental. It is for this reason that Tunis, built Phoenix-like out of the ruins of mighty Carthage, still retains many of the ideas, modes and customs of that earlier civilisation. Indeed, the besom of progress has but little disturbed, throughout the length of North Africa, the conditions of life of two thousand years ago. Along the shores of the Mediterranean one thing that strikes the most casual observer is the classic elegance of the humble pots and pans of domestic purpose in daily use from the Pillars of Hercules to its eastern extremity. It is obvious that all have a common origin, easily accountable, having in mind the facilities for maritime intercourse afforded by that middle sea. Pottery, that earliest of the arts, has from time immemorial been actively pursued in this region, and Tunis to this very day is famous for its household pottery. The ware is made not actually in the town of Tunis, but at Nabeul, not far away. The glazed pottery of Nabeul is very distinctive in character, the colouring being a rich green and yellow; a quaint

Hosted by Google

fashion obtains there of glazing dishes and bowls half in the one colour, half in the other, with agreeable effect.

But it is of the unglazed pottery of Nabeul that I wish particularly to write. The cups, the bowls, the vases and water-bottles are of porous body, admitting of fairly rapid evaporation, and consequently keeping the liquid contents at a gratefully low temperature, a desirable consummation in a land where the climate is hot and water the universal beverage.

It is particularly the decoration and the mode of its execution that is so exceedingly interesting, pointing as it does to the survival of a most primitive method, certainly handed down from the days of Phœnician civilisation, when Carthage was the great mercantile metropolis of the known world.

The very archaic Greek character of its black decoration was what first attracted my attention; very similar in character to Mycenean in the British Museum, the decoration in both being evidently a colouring matter applied *after* the firing of the ware. My guide, after expressing surprise that such common pottery should interest me (you buy specimens for a penny or two), informed me that the black decoration could only be executed in the springtime, as the colouring matter had to be obtained from the juice of a certain tree. He, in due course, took me into the country and gathered the green pods of the wild caroub tree; the juice expressed from the pounded green pods was, he told me, the staining material used. I tried it and failed.

Later in the season I had many opportunities of witnessing the actual operation. The painter, seated on a door-step in the shade, very rapidly and cleverly executed the design that took his fancy. The horizontal bands were deftly made by turning the bottle or cup on his knee, whilst he held the brush, loaded with the vegetable juice, in the proper position; then the lattice work, or honeysuckle, or bird, or such other time-honoured design, was promptly added, and the object left to dry in the sun for a few minutes. The decorated portion was scarcely distinguishable from the clay body in colour previous to immersion for a short time in a bucket of water at the artist's side. When withdrawn, the decoration had turned a beautiful black.

After some persuasion, I induced the painter to sell me a bottle of the caroub juice. A timely-offered cigarette made the artist expansive, and he remarked: "You require something besides the bottle of juice to turn the paint black; there is more than water in the bucket I dip the pots in. I'll give you some of the stuff you must mix with it." Thereupon he went to his room and brought me a packet of crystals, which proved to be sulphate of iron (in Arabic, *zeudj*), and instructed me as to the quantity I should use I then knew why my own experiments had failed, and was at the same time profoundly struck with the unique process, one so primitive and yet so sufficing and so admirably adapted to its purpose, for it must be borne in mind that decoration which would interfere with the porosity of the ware would be undesirable; consequently any vitrified, fired decoration would, of necessity, be barred.

Apart from this, the close likeness, both in the manner and the matter of the decoration, to the early Græco-Egyptian pottery was strongly impressed upon me, particularly as in the Bardo Museum at Tunis and the Museum of the White Fathers at Carthage, specimens four thousand years old, dug up on the latter site, were in evidence for comparison.

In conclusion, I must say I was surprised at being told by Tunisians themselves, that until I had investigated the process of the decoration of this particular ware, no one had evinced any interest therein. Knowing as we do how slowly the East changes, and how unique, as far as I am aware, is the process of this decoration, is not this obviously a craft survival handed down through the centuries and identically the same method as that pursued by the Phœnician predecessors of the present-day Tunisian?

It is pleasant to think that Dido was probably refreshed with a draught of cold water, poured out of a similar bottle into a similar cup to those which are in use to-day on the site of the city of her former greatness.

HERMAN HART.

PAPAYA OR PAWPAW.

I notice in the *Journal* of March 1st that Sir George Birdwood has written a short paragraph on the Papaya or Pawpaw. It is very largely grown in most gardens in this province, and many natives are now cultivating it. It is generally known here also as Pawpaw, though I have endeavoured to induce people to call it Papaya, but without success.

Where fruit, except bananas, and vegetables are scarce, we look upon the fruit as delicious, and it is a great digestive.

It may not be generally known, and perhaps Sir George Birdwood may not be aware of the fact, that by wrapping up a joint of meat in the leaves of the Papaya for two or three hours, the toughest meat becomes very tender.

The African kuku (chicken), even a champion sprinter of many years' standing, can be made in this way as tender as a spring chicken.

R. C. R. OWEN,
Governor, Mongalla Province, Sudan.

THE ROYAL SOCIETY OF ARTS AND FORESTRY.

A reader of the *Journal*, who has been for twenty-five years a near neighbour of Windsor Park and Forest, writes:—

"In the very interesting ninth section of the history of the Royal Society of Arts published in your *Journal* of July 12th, Sir Henry Trueman Wood mentions that complaints of the lack of

Hosted by Google

timber were rife as far back as the Restoration. But Mr. Menzies, in his 'History of Windsor Park and Forest,' mentions that, still further back, Queen Elizabeth was much perturbed at the prospect of the destruction of the forests where the oaks for the British Navy were grown.

"When the invasion of the Armada was threatening, she gave special orders that the coasts of the Bristol Channel and the English Channel should be specially protected, because the Spaniards would be sure to destroy the timber in the Forest of Dean, and she also caused then and there to be planted a considerable area of oak plantation in Windsor Great Park. Mr. Menzies is able to identify almost the exact site of this plantation, and its hoary survivals."

OBITUARY.

Earl Ferrers.—Earl Ferrers died at his residence, Staunton Harold, Ashby-de-la-Zouch, on July 26th. He was born in 1847, and succeeded his father in the peerage at the age of twelve. He was educated at Trinity College, Cambridge. Lord Ferrers was a Knight of Justice of the Order of St. John of Jerusalem, Provincial Grand Master of Freemasons of Leicester and Rutland, J.P. and D.L. for Leicestershire and Staffordshire, and J.P. for Derbyshire. He became a member of the Royal Society of Arts in 1880.

Frederic Julius Macaulay. — Mr. F. J. Macaulay died on July 18th at his residence on Clapham Common at the age of eighty-two. He was connected with the London and South-Western Railway for over sixty-one years. Entering the secretary's department at Waterloo, he was appointed assistant secretary in 1865, and secretary in 1880, finally becoming a director in 1898. In addition to his work on the staff of the London and South-Western Railway, Mr. Macaulay was connected with various other railway enterprises. He was one of the promoters of the Waterloo and City Electric Railway, and of the Axminster and Lyme Regis Light Railway. He had been a representative director of his company at the boards of the West London Extension, the North Cornwall, and the Somerset and Dorset Railway Companies, and was a representative member of the Railway Companies' Association. He also acted for a short time as Chairman of the Demerara Railway Company. His interest in the South-Western Railway staff was indicated by close identification with the benefit funds and friendly societies which its members established. He was also on the governing body of the Railway Benevolent Institution. Mr. Macaulay was an Associate of the Institution of Civil Engineers, a Fellow of the Royal Geographical Society, the Zoological Society of London, and the Institute of Directors. He was a Past Master in English Freemasonry, and a freeman of the City of London. He became a member of the Royal Society of Arts in 1896, and as long ago as 1856 a letter from him was published in the *Journal*, in which he urged the establishment of a system of examination of classes by the Society.

NOTES ON BOOKS.

Lectures on British Commerce. By the Right Hon. Frederick Huth Jackson, G. Armitage-Smith, M.A., D.Litt., Robert Bruce, C.B., and others. London: Sir Isaac Pitman & Sons, Ltd. 7*s*. 6*d*. net.

This volume contains ten of the lectures which were delivered by well-known authorities at the meeting of the International Society for the Promotion of Commercial Education held in London last year. In the first, Mr. Huth Jackson gives an admirably lucid account of the Bank of England. An abstract of the lecture was printed in the *Journal* last year. Dr. Armitage-Smith follows with a succinct description of the British system of taxation, and an excellent epitome of the postal organisation, with special reference to the London Postal Service, is given by Mr. Robert Bruce, C.B., Controller of the London Postal Service. The remaining lectures are: "London as a Port," and "The Machinery of Marine Insurance," by Douglas Owen, Barrister-at-Law, late Secretary of the Alliance, Marine and General Assurance Co.; "British Shipping," by W. E. Barling, Editor of the *Shipping Gazette;* two lectures on fire, life, industrial and other kinds of assurance, by J. J. Bisgood, B.A., Secretary in London of the Edinburgh Life Assurance Company; "The Economic Position of the Coal Industry of the United Kingdom," by Allan Greenwell, F.G.S., A.M.Inst.C.E., Editor of the *Colliery Guardian;* and "The Woollen Industry," by James Graham, Secretary for Education, City of Leeds.

These, of course, form but a very small portion of the lectures which were delivered at the meeting, but they have been carefully selected as excellent examples of the style and character of the others. They are designed in the main for a foreign audience who, although possessed of a general economic and commercial education, have no detailed knowledge of English conditions. The organisers of the London meeting of the International Society for the Promotion of Commercial Education were certainly fortunate in the lecturers whose services they secured; and it is gratifying to learn from the introduction by the Hon. W. Pember Reeves, that their efforts were rewarded by a large and eager attendance of foreign students. It was an excellent idea to publish a selection of the lectures in permanent book form.

Photographic Copyright. By George E. Brown, F.I.C., and Alexander Mackie. London: H. Greenwood & Co. 1*s*. net.

The Copyright Act, 1911, came into force on July 1st, 1912, and introduces important reforms in the

Hosted by Google

law of the subject. The appearance of this volume is, therefore, very opportune. It is issued from the office of *The British Journal of Photography*, and is a working guide among the intricacies of copyright law for any photographer having occasion to dispose of the rights of reproduction in his photographs. The rights of the photographer in reference to the photographs taken of sitters in various circumstances and the rights, on the other hand, of sitters in their photographs are explicitly dealt with, so that the volume forms a reliable aid to portrait photographers in deciding business disputes. Conditions of obtaining copyright in foreign countries, and particularly in America, are fully dealt with. The pages are freely cross-referenced, and a full index is provided, while the Act itself, or rather such part of it as refers to photographic copyright, is printed as an appendix. The subject is from its nature somewhat difficult and intricate, but the authors have succeeded in dealing with it in a simple and comprehensible manner.

GENERAL NOTES.

The Institute of Metals.—Next month the Annual Autumn Meeting of the Institute of Metals will be held in London for the first time since the Institute's formation in 1908. In that year the Institute met in Birmingham; in subsequent years meetings were held in Manchester, Glasgow, and Newcastle-upon-Tyne. Arrangements for the meeting to be held on September 25th and 26th are in the hands of an executive committee composed of the London Members of Council of the Institute. The meeting, for which ten papers have been presented, will open at 10.30 a.m. on Wednesday, September 25th, at the Institution of Electrical Engineers, Victoria Embankment, W.C. During the morning a series of papers will be read and discussed, Professor W. Gowland, F.R.S., President, being in the chair. In the afternoon members will proceed either to the works of Messrs. Fraser & Chalmers, Ltd., Erith, or to the National Physical Laboratory, both of which will be open to their inspection. In the evening there will be a reception, by the President, of the members and their ladies, which will take place at the Royal United Service Institution, Whitehall, S.W. On Thursday, September 26th, papers will be read and discussed at the morning session of the Institute at the Institution of Electrical Engineers, and in the afternoon alternative excursions will take place, one being to Woolwich Arsenal by special steamer from the Embankment, and the other being a visit to the Brooklands motor racecourse and aviation ground, special motors being provided for the conveyance of the party. Anyone desirous of taking part in the meeting should communicate with the Secretary, Mr. G. Shaw Scott, M.Sc., Caxton House, Westminster, S.W.

Importation of Italian Rice to the Argentina.—The decline in the quantity of rice imported to the Argentine Republic from Italy is causing some anxiety among the rice-growers in the Provinces of Novara and Vercelli. The imports of this cereal, which amounted to 67,167 tons in 1907, fell gradually to 44,700 tons in 1910, a decrease of 33·45 per cent., or one-third in three years. This decline may, to some extent, be attributed to the competition from Egyptian and Asiatic-grown rice, a great proportion of which is imported with the husks, as *riso mezzo lavorato;* this pays a lower rate of duty, viz., 270 francs per quintal (about 1*s.* 1¾*d.* per cwt.), as compared with the *riso lavorato*, or perfectly clean Italian article, which pays 10·80 francs per quintal (4*s.* 5*d.* per cwt.). 92 per cent. of the rice imported from Italy belongs to this class. A large quantity of rice is now grown in the Province of Buenos Ayres, and naturally pays no duty. It is probable that this tariff, which falls heavily on Italian-grown rice, may be modified in view of a possible reduction of the duty now levied in Italy on meat imported from Argentina.

Departmental Committee on Flax Spinning and Weaving.—The Home Secretary has appointed Commander Sir Hamilton Freer-Smith, C.S.I., R.N., formerly Superintending Inspector for Dangerous Trades (Chairman), Professor J. E. Petavel, F.R.S. (Professor of Engineering in the University of Manchester), Professor J. Lorrain Smith, F.R.S. (Professor of Pathology in the University of Manchester), Mr. G. Herbert Ewart, of Messrs. William Ewart & Son, Limited, Bedford Street, Belfast, and Mr. Henry Cummins (Chairman of the Weavers and Winders Trade Union, Lurgan), to be a committee to inquire and report what amendment (if any) of the regulations for the spinning and weaving of flax or tow and the processes incidental thereto, is expedient in view of the Report of the Departmental Committee on Humidity and Ventilation in Cotton Weaving Sheds, or on other grounds. Mr. D. R. Wilson, H.M. Inspector of Factories, has been appointed Secretary to the Committee.

Production of Precious Stones in Siam.—Some years ago it was estimated that five-eighths of the world's supply of sapphires came from the alluvial workings of south-eastern Siam, where these gems have been sought after by Shans and Burmese for many generations. Statistics as to the yearly amount of sapphires produced are not available, as they are free of both inland taxes and export duties. Rubies are found in the districts of Chantabun and Krat in eastern Siam, but those of good colour are small, while the larger sized ones are of poor colour, but it is said that the better quality of rubies are sent overland to Burma, and are there sold as Burmese rubies. The gem industry is in the hands of Burmese and Shans, and the alluvial deposits are washed by hand in the streams. The trade in gems is chiefly carried on by natives of India, Burma, and Ceylon.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

THE MATERIALS AND METHODS OF DECORATIVE PAINTING.

By Noel Heaton, B.Sc., F.C.S.

Lecture II.—Delivered March 25th, 1912.

Fresco and its Modifications.

In our brief historical survey last week we arrived at the result that the works of the past were produced by various methods of painting, which we may tabulate thus:—

A. Pigments incorporated with the ground, no medium being employed . . . Fresco.

B. Pigments fixed to the ground by means of an organic medium:—

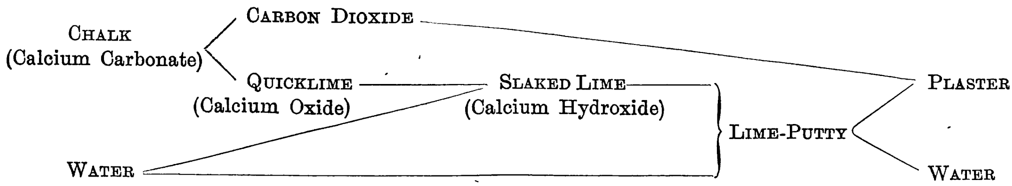
Size or glue soluble in water . .	Distemper.
Emulsion miscible with water, but insoluble on drying	Tempera.
Oil "drying" by chemical action .	Oil painting.
Melted wax	Encaustic.

We have now to consider these processes individually and discuss the problems involved in their use, which in each case divides itself under three heads:—(1) the ground to paint on; (2) the pigments; (3) the medium or vehicle. My purpose this evening is to consider in detail the first of these two main branches—that which we know as fresco.

The essential characteristic of fresco painting is that the binding medium is inorganic, and, in fact, part of the ground itself, so that the third factor is really eliminated, no medium whatever being actually mixed with the pigments on application, other than pure water. Everything depends, in fact, on the nature of the ground in fresco painting, and in order to have a clear idea of the possibilities and limitations of the process it is essential to know something of the principles involved in this peculiar action of the fixing of the pigments by the hardening of the plaster. The ground of

Hosted by Google

fresco painting is essentially some form or other of lime plaster, the production of which depends upon the cycle of changes indicated in the diagram:—



The familiar fact that chalk, on being heated, is converted into quicklime is explained by its chemical composition, which is that of lime, or calcium oxide, in combination with a substance which results from the burning of coal, known as carbon dioxide. But the combination between these two substances is not very strong. When, for instance, chalk is heated in a lime-kiln the heat destroys the combination—the carbon dioxide, being a gas, escapes up the chimney, leaving the lime behind. We call this "quick-lime," because it is chemically active, or eager to combine with anything else—more particularly, as you are aware, if you add a little water to it, the two combine together chemically to form a new substance which the chemist calls calcium hydroxide, and the builder's foreman "slaked lime."

The power of quicklime for combining with water is, however, strictly limited; when half a hundredweight of quicklime has combined with eighteen pounds of water its powers are at an end, the whole of it being converted into slaked lime. You must understand that this slaked lime would be perfectly dry; both the water and the quicklime have ceased to exist.

If a greater proportion of water is used than is required to effect this chemical reaction, a small proportion of the slaked lime first formed will dissolve in the excess of water, but only a small proportion, and the remainder will mix with this solution mechanically to form a stiff paste, which is familiarly known as "lime-putty." This lime-putty is the material used in making lime-plaster, and the cause of its operating in this way is due to a reversal of the process I have just described.

When the lime-putty is spread out on a wall, or exposed to the air in any way, first of all the water commences to evaporate. This naturally results in some of the slaked lime being deposited from solution, which locks together, as it were, the solid particles already present, causing the whole mass to stiffen, or "set" into a firm mass. Now the carbon dioxide has been hovering around in the air all this time, and the moment you leave the plaster alone, and there seems a prospect of peace and quietness, it gradually combines with the lime again, with the result that finally the whole mass of plaster is re-converted into its original form, and becomes once more a hard mass of insoluble chalk.

That is the explanation of the setting of lime-plaster, and if I have made it clear you will readily understand how fresco painting becomes possible, for after the first setting of the plaster has taken place you have a practically solid mass of soluble slaked lime saturated with a solution of the same substance. If you now make any pigment into a paste with pure water and apply this to the surface every particle of the pigment will be saturated with the solution of slaked lime in the same way, and as this is on the surface it first hardens by evaporation of the water, and is almost at the same time attacked by the carbon dioxide and converted into chalk, the result being that every particle of pigment is actually surrounded by and incorporated with the substance of the plaster, the whole forming one rigid mass.

The extent to which the pigments placed on the surface of the plaster in fresco painting are actually incorporated with the substance of the plaster itself, can be clearly seen from the photomicograph I now show you of a section of the surface of a fresco painting.

I have assumed for the moment, in order to make my description clear, that the plaster consists entirely of lime-putty, without any admixture, as it is on the reactions that take place in this material that the setting depends. It is a generally accepted fact, however, amongst practical plasterers that a plaster composed entirely of slaked lime is not satisfactory, and that some inert material must be mixed with the lime in order to produce a satisfactory plaster. It is true that the plaster used by the prehistoric fresco painters of Knossos is composed entirely of carbonate of lime; although, at first sight, this would seem to indicate that it was originally composed entirely of slaked lime, that is not necessarily the case. It is possible that the

Hosted by Google

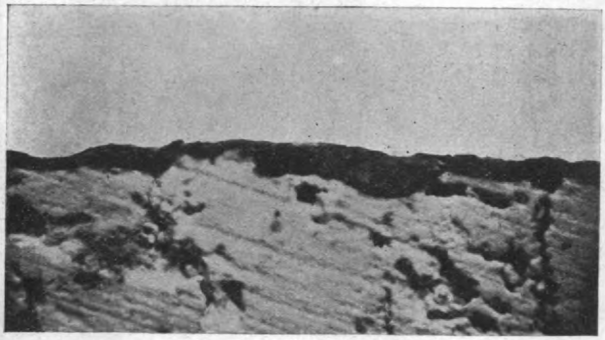
inert material consisted of the same limestone from which the lime was prepared merely reduced to powder, without being burnt.* The Roman craftsmen mixed their lime-putty with a considerable proportion of coarsely-powdered marble or similar material, varying in nature according to the resources of the district in which the work was executed.

This practice was continued by the mediæval fresco painters, as we learn from practical examination and from the various treatises on the craft, notably that of Cennino Cennini, whose methods have formed the model on which such examples of fresco as have been produced in modern times have been based.

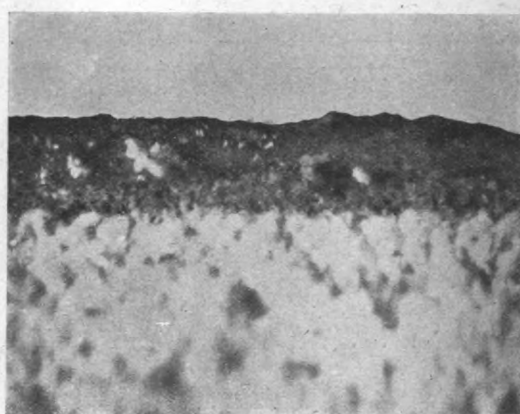
Briefly stated, the method adopted, as described by Mrs. Sargant Florence,† is as follows. The wall is first "rendered" with a coarse rubble plaster composed of lime and pounded brick or pottery; the intermediate plaster (or Arricciato, as it was called by the Italian workers), composed of lime-putty and sand, is laid on this as soon as the initial setting has taken place, three or four coats of this being frequently applied. The wall is thus brought to a dead smooth surface to receive the final thin coating of fine plaster or intonaco on which the painting is executed. This last coat is composed of lime-putty and finely-powdered white marble, and is, as a rule, little more than an eighth of an inch in thickness; with such a thin coating the process of initial setting is comparatively rapid, and in order to secure thorough incorporation of the pigments with the ground, it is necessary that they shall be applied within a few hours of laying the intonaco. This necessitates laying the intonaco in sections, only as much being put on as can be painted in one day, this amount varying of course with the intricacy of the portion to be painted; in the finished work the line of junction between each successive day's work can often be clearly seen on close examination, as in the mediæval example I now show you.

Very little has been done in modern times towards investigating the possibilities of improvement in the plaster used for fresco work, and the use of such materials as asbestine, or finely-powdered asbestos in replacement of marble dust. There is, in fact, a wide field of research open in the direction of modifying the composition of the plaster with a view to making it more easy to work with, and more especially with a view to making it more resistent to decay. Modern workers in fresco, as a rule, follow doggedly the directions given by Cennino Cennini, and endeavour to reproduce the tradition of mediæval Italy, without any attempt to enlist the resources of modern science on their behalf.

I shall refer to what has been done in this direction later, but before doing so I must say a few words about that other great factor in the



a



b

FIG. 1.

a. Section of surface of fresco painting (× 50), showing how the pigment penetrates the surface.

b. Comparative section of painting in oil on plaster (× 100), showing the sharp line of junction between the paint and the ground.

* Since these lectures were delivered I have completed an investigation of the frescoes discovered at Tiryns, and have succeeded in obtaining definite proof that this was the practice followed in their execution; the bulk of the plaster was prepared by mixing powdered limestone and lime-putty, pure lime being used, however, to produce the final smooth surface for painting on. It is quite conceivable that the later practice of adding marble dust to the lime originated in the fact of this marble having been used as the source of the lime.

painting which I have so far ignored—namely, the pigments.

It is obviously impossible for me to attempt any detailed description of the nature and properties of pigments in the time at my disposal, nor is it necessary for me to do so, as many excellent works have appeared on the subject. I will merely attempt to remind you of the main facts concerning them by means of the accompanying summary:—

SUBSTANCES USED AS PIGMENTS.

Class I.—Metallic Oxides and Salts.

Division 1.—Mineral Whites.

Silicon	Silica Asbestine (*powdered asbestos*)
Barium	Barytes (*Blanc fixe: Process White*)
Calcium	Chalk (*Whiting: Paris White*) Terra Alba (*Gypsum*)
Aluminium	Alumina China Clay (*Kaolin*)
Zinc	Zinc Oxide (*Chinese White*)

Intermediate—Earth Colours.

Mineral Whites stained by iron and manganese	Ochre Sienna Umber Terreverte Vandyke (artificial) Naples Yellow (artificial)

Division 2.—Coloured Compounds.

Iron	Iron Oxide (*Indian Red, Venetian Red, etc.*)
Manganese	Manganese Brown
Copper	Malachite Egyptian Blue
Cobalt	Aureolin Cobalt Blue Cobalt Green Cerulean Blue Smalt
Chromium	Chromium Oxide Viridian Chrome Yellows
Lead	Red Lead White Lead (*Flake White*) Sublimed White Lead Naples Yellow (original)

Class II.—Sulphur Compounds.

Lapis Lazuli
Ultramarine (*New Blue: French Blue*)
Cadmium
Vermilion
King's Yellow
Lithopone

Class III.—Semi-Organic Compounds.

Prussian Blue (*Chinese Blue: Antwerp Blue*)
Emerald Green
Verdigris

Class IV.—Organic Substances.

Lamp Black (*Vegetable Black*)
Ivory Black
Graphite
Asphaltum (*Bitumen: Mummy*)
Bistre
Vandyke Brown (natural)
Sepia
Carmine
Gamboge
Indigo
Indian Yellow (*Puree*)

Class V.—Lakes.

Natural	Crimson Lake: Madder Lakes Italian Pink: Sap Green, etc.
Artificial	Lakes from Aniline and Alizarine dyes, etc.

We are more particularly interested this evening in the selection of pigments for fresco painting. The great point to bear in mind in considering the advisability of using any pigment for this process is the energetic chemical nature of the caustic lime to which the pigments have to be applied. Anything of an organic nature is immediately destroyed, which rules out at once the large number of pigments comprised in Classes III., IV., and V., with the exception of the blacks produced from carbon itself (lampblack, vegetable black, ivory black, etc.). Also you have to bear in mind the fact that the pigments are exposed under the most drastic conditions of exposure possible—laid on a freely absorbent surface and exposed to light and air without any protection except that afforded by the film of porous lime around them. Only pigments of the highest order of permanency are, therefore, possible, and even those in Class I. that are liable to change in impure air, such as white lead, must be avoided.

In the following list I have indicated which of the substances referred to in the previous classification are available in fresco painting and which must be avoided. The intermediate column, headed "may be used," contains certain pigments which have been extensively utilised in fresco, as they are perfectly stable against the effect of caustic lime, but which, nevertheless, I consider had better be avoided in work executed under modern conditions, as they are liable to be affected by an urban atmosphere containing sulphuric acid and other sulphur compounds, or to affect other pigments injuriously. Such a substance as ultramarine, for example, is perfectly fast to light and alkali, and can even withstand heat without injury, and on account of its beauty was rightly cherished almost above all other pigments in mediæval

times; although one of the most durable of pigments under normal conditions, however, it has one weakness in common with the plaster itself—that of being destroyed by the weakest acid, and therefore, as we shall see in a moment, it is quite unreliable in our modern contaminated atmosphere. This affords an excellent example of the danger of blindly following mediæval traditions in modern work.

of the thorough slaking of the lime before use, but without, I think, always appreciating the principle involved, because they insist also on the tradition derived from mediæval times that the longer the lime-putty is kept the better it will be for the purpose. It is true that thorough slaking—that is to say, the conversion of every single particle of calcium-oxide into calcium-hydrate by combination with water, is of the

	Freely Used	May be Used	Inadmissible
Class I.	Zinc Oxide Ochre, Sienna, Umber — Raw and Burnt Artificial Earths Indian Red Venetian Red Light Red Cobalt Green Cobalt Blues Smalt Egyptian Blue Chromium Oxides	Terreverte Malachite Red Lead Sublimed White Lead Naples Yellow	Aureolin Chromes White Lead
Class II.	None	Vermilion Ultramarine	Cadmium Lithopone King's Yellow
Class III.	None	None	All
Class IV.	Lampblack Ivory Black Graphite	None	All others
Class V.	None	Madder Lakes	All others

So much, then, for the materials employed in fresco painting; it would be beyond my scope to discuss in detail the preparation of the plaster and the laying on of the pigments, but I would like to refer briefly to certain technical aspects of the process. In the first place, all writers on fresco insist, and rightly insist, on the importance

utmost importance. To make sure of this, it was a perfectly sound practice to mature the slaked lime in olden days, when mixing had to be done by hand, and no means were available of reducing the lime to a uniformly fine powder. But I am convinced myself that more thorough and better slaking could be obtained in a

Hosted by Google

comparatively short time by mechanical means; there is no reason why the slaked lime should not be matured by grinding it in water for a few days in a ball mill (a rotating cylinder filled with steel balls), when every particle would inevitably be brought in contact with the water, and a far finer and more uniform product obtained. Still more important is it to bear in mind that such mechanical slaking obviates all risk of partial carbonating of the lime-putty before use, which is liable to occur when it is kept for a prolonged period in the open. From the description given of the chemical action involved in the process it will be seen that any such carbonation would seriously weaken the plaster and result in the pigments not being firmly secured to the surface.

The composition and purity both of the lime and the "aggregate" or inert material added to it, again, are of importance, a point that is little realised by artists—for example, an excessive content of magnesia in the lime would impair its durability; in the execution of an important work it is well worth while to ascertain the composition of the lime used, and to know exactly what one is working with.

Although it is impossible to remove a pigment once put on, one pigment can be painted over another as long as the plaster is fresh, that is, before the carbonation of the surface has proceeded to any extent and an ample supply of solution of hydrate is available, to soak through the pigment and act as a binding agent. A certain amount of painting can also be done after the plaster has dried by saturating it afresh with lime-water and painting with pigment mixed with lime-water. Work can, in fact, be executed entirely in this way, a modification of the process occasionally employed by mediæval painters under the name "fresco-secco." This method is not, however, to be recommended for general use, as it is impossible to secure quite such thorough incorporation of the pigment with the ground by its means.

There can be no doubt as to the charm of a painting properly executed by this fresco process. It cannot be denied, however, that to modern ideas it is by no means an easy process to work in. The need for careful preparation of the design beforehand, so that the actual execution of the painting may be carried out with the necessary certainty and directness, the difficulty of preparing the painting surface from day to day and skilfully masking the necessary joints between one day's work and the next, the allowance to be made for the general lightening in tone of the pigments in drying—all these limitations are irksome to the modern artist, accustomed to the facility of painting in oil, and they demand for their successful solution a skill and craftsmanship which can only be attained by patient labour and the skill born of experience and practice—practice which, unfortunately, is difficult to attain at the present time, when commissions for fresco are few and far between.

These difficulties are, however, only matters of experience, and can be quite overcome by sufficient practice. But, apart from these limitations of technique, one also has to face the economic difficulties of fresco painting, the fact that the work must be done entirely on the spot, and the building must be at the disposal of the artist for a prolonged period serves, perhaps, more than anything else, to limit the opportunities for fresco painting, for under the modern conditions it is not always possible to segregate even a new building from its use for the necessary period. One might, however, hazard the suggestion that even in such cases the artist might sometimes profit by the example of the fresco painters of the days of King Minos, executing the work in framed panels which could be set into the wall bodily. Here, again, is scope for development and for co-operation between artist and chemist.

The most vital point to consider, however, is the question of the durability of fresco under modern conditions of exposure. There can be little doubt that under normal atmospheric conditions fresco is the most durable process of decoration imaginable. The pigments are of necessity limited to those which are practically imperishable, and a well-prepared plaster is proof against extremes of heat, cold and damp, which rapidly destroy any organic medium; there is little doubt, in fact, that the process was evolved as a means of protecting buildings against the disintegrating effect of weather, and the frescoes of the palace of King Minos, where preserved from the disastrous effect of the conflagration in which the building perished, have come down to us intact after some 3,000 years of exposure.

There is no doubt, moreover, that in ancient times, when fresco painting was the ordinary method of house decoration, the paintings outlasted their use, for it is quite a common thing to find the wall surface re-decorated, the surface being hacked over to provide a key, saturated with lime-water and a fresh layer of plaster added. I have found examples of this in all periods, the point being that the underneath painting is in quite a fair state of preservation,

Hosted by Google

the only possible explanation being that it was covered, not because it was decayed, but because the occupiers of the house were tired of the design and wanted a fresh scheme of decoration. This practice was so common in this country in Roman times that examples of it are to be found in almost every museum. In the museum at Colchester, for example, are to be seen a number of specimens of fresco painting discovered in the ruins of a Roman villa, many of which exhibit three and even four paintings super-imposed in this way.

It is a great mistake to suppose, as many do, that the natural climate of this country is destructive to fresco painting. Unfortunately one must at the same time admit that the atmosphere of our modern towns in its present condition is extremely injurious to such work, for fresco has an extremely weak point—it is affected by the slightest trace of acid. This fact will be readily appreciated if you bear in mind the readiness with which the carbonic acid is removed from its combination with the lime, owing to its gaseous nature; a removal that is accomplished not only by heating, but by the action of any acid that is stronger than carbonic acid; such a substance, for example, as sulphuric acid, which decomposes carbonate of lime rapidly, driving off the carbon dioxide and combining with the lime to form gypsum. When this action takes place on the surface of a fresco painting decay inevitably results, because not only is the binding between the particles of pigment destroyed, but the whole substance of the plaster is gradually disintegrated. Now the atmosphere of our modern towns is heavily

charged with sulphuric acid as a result of the continual combustion of coal. It will be well understood, therefore, that apart from the concomitant evil of smoke, which rapidly covers a porous surface like fresco with grime and obscures its beauty, the effect of this contamination of the atmosphere is disastrous, and renders some protective after-treatment an imperative necessity, if durability is to be secured. The difficulty is to find any method of treatment which will effectually protect the surface from the action of the acid whilst preserving the inimitable quality of the painting, which is destroyed by any treatment such as sizing or varnishing, apart from the fact that these prove very inefficient for the purpose. Fortunately we have one method of preservation which to a large extent combines the maximum of protection with the minimum effect on the quality of the surface, and that is the encaustic process introduced by Sir Arthur Church in connection with the restoration of the frescoes in the Houses of Parliament. The treatment is carried out by covering the surface with a mixture of one part of hard paraffin wax with four parts of toluol, in the form of a kind of paste or ointment, and afterwards, when the volatile tuluol has evaporated, driving in the residual paraffin by means of heat. Of course this impregnation process is not a matter for unskilled hands; some care and experience is required for its proper performance.

This treatment is but a palliative; it inevitably entails some disadvantage, and under normal conditions fresco is better without it. But we must frankly realise that under modern conditions we have to face a choice of two evils—gradual but sure destruction, or a slight loss of quality, and the necessity for periodical cleaning to remove the dirt which adheres to, but does not penetrate, the waxed surface. I am strongly of the opinion myself that every fresco painting executed in this country should be subjected to this treatment, even in rural districts, for we must bear in mind that, although the vast bulk of impurity is produced in the large towns, it is distributed over wide areas by the movement of the air, and every little village, moreover, is a local source of contamination, so that one has to be remote indeed to obtain a perfectly pure air.

Let us now consider the possibility of modifying the process of fresco painting so as to overcome these limitations of durability. As far back as 1825 Fuchs proposed to anticipate the action of the sulphuric acid, as it were, by attacking the carbonate of lime directly it was formed, and deliberately changing it into another compound which could resist the action of sulphuric acid. This was accomplished by means of the chemical reaction expressed in the diagram:—

$$\text{Water Glass}\left\{\begin{matrix}\overbrace{\text{Silica}\qquad\text{Lime}}^{\text{Silicate of Lime}}\\ \underbrace{\text{Soda}\qquad\text{Carbon Dioxide}}_{\text{Carbonate of Soda}}\end{matrix}\right\}\text{Plaster}$$

The substance known as water-glass, because it has all the appearance of glass but is soluble in water, is prepared by combining soda and sand by heating them together in a furnace; when a solution of this substance is applied to the surface of a lime plaster, a mutual exchange takes place, with the result that a new substance—silicate of lime—is produced, which acts as a binding agent for the pigments, and has the advantage that it is proof against attack by sulphuric acid. Unfortunately we have to bear in mind the fundamental law of Lavoisier, on which the whole science of chemistry is based: matter is indestructible, and every particle of a substance taking part in a chemical reaction must be accounted for. We have to reckon, then, with the soda, which was combined with the silica we wanted, in order to render it soluble in water and available for attacking the plaster; discarded after having served its purpose, it combines with the carbon dioxide to form carbonate of soda, which must be entirely removed to render the operation a success, for if it is left in the plaster it is certain to cause unsightly efflorescence by crystallising out on the surface, and moreover is liable to attack the plaster again, causing a reversal of the action, the remedy being thus worse than the disease. The entire removal of this substance is, however, a very great difficulty, and its presence is sufficient to render the treatment in this form a failure.

But from this method of treating the plaster there has been evolved the process of *stereochromy,* which is not so much a modification of fresco as an entirely different process, entailing a different although similar technique and method of working. The stereochrome process was first employed in this country in the later decorations of the Houses of Parliament, after fresco had been abandoned on account of the difficulties encountered in its execution, due to lack of technical knowledge. The best-known examples are the immense paintings by Maclise in the Royal Gallery—the famous "Meeting of Wellington and Blucher after Waterloo," and the "Death of Nelson," and the painting by

Hosted by Google

Herbert, "Moses bringing the Tables of the Law." These paintings were, however, by no means a perfect success—restoration was necessary within ten years of execution and further restoration was carried out at intervals. In 1894 Sir Arthur Church found them obscured in many places by an efflorescence of sulphate of soda and lime, indicating that the main cause of the trouble was the difficulty of removing all traces of alkali from the painted surface.

[Slides of the paintings referred to, and other modern examples, were here thrown on the screen.]

The original stereochrome process employed in the production of these works was considerably improved by Keim some time later. A full description of this process was given in this room some years ago,* so it is unnecessary to describe it in detail.

A painting of extreme durability is produced by the process if the cycle of operations involved in this process is carried out properly, as the final plaster is not only unaffected by acids but is extremely hard, and only slightly absorbent. Although this process has the added advantage over fresco that the preparation of the ground, the fixation of the pigments and the actual paintings are divided into three distinct operations, the execution of a large painting is, nevertheless, an arduous undertaking, on account of the numerous operations involved, and the difficulty of removing all traces of the soda, by laborious spraying with distilled water, an operation on which, as already explained, the success of the painting to a large extent depends. This process, in fact, is essentially a case for division of labour, the artist requiring the assistance of a highly-trained craftsman, preferably with some scientific knowledge, to ensure the success of the preparation and treatment of the ground.

We may ask, however, whether it is not possible to modify the composition of the plaster in fresco painting, so as to retain the comparative simplicity of producing the finished painting in one operation, without the necessity of subsequent spraying, whilst at the same time obviating the dangers inherent to carbonate of lime plaster. If one could obtain, for example, a brilliant white plaster with a composition resembling that of a slow-setting Portland cement, the difficulty would be solved; but this is not possible in the present state of our knowledge. There are, however, very great possibilities in the use of a cement of an entirely different description, depending on a curious reaction that takes place when oxide of zinc is mixed with a solution of chloride of zinc. If these two substances are mixed in the right proportions, they combine together slowly to form a substance known as zinc oxychloride, the composition being intermediate between the two, and in so doing set into a hard mass, thus forming a durable cement, which is largely utilised for many industrial purposes. Such a cement is not decomposed by sulphuric acid like carbonate of lime plaster, for the reason that it is a compound of an acid equal to it in strength.

There seems no reason why a process of painting which would bring fresco into line with modern requirements should not be based on this reaction, if only the opportunity for the necessary systematic investigation were forthcoming, and I venture to suggest that so far from fresco painting being a dead letter, as is so often suggested, the possibilities in the way of development in this direction which have never been exploited are sufficient to justify the hope that it may become once more—even under present conditions—the most durable as well as the most beautiful process of painting.

* This *Journal*, December 4th, 1895. I am indebted to Mrs. Lea-Merritt for much information on the practical working of this process and assistance in the preparation of the lecture.

THE TURTLE INDUSTRY OF MEXICO.

The rivers and fresh-water lagoons at some distance from the Mexican coasts literally swarm with turtles of the genus "Nanemys." They are found even at an altitude of about three thousand feet above sea-level. They attain a considerable size, some of them reaching a weight of sixty-five or even seventy-five pounds. This turtle is considered to be a dainty as well as a staple food all over the Gulf Coast region, and is annually taken in great numbers. According to the United States Consul at Vera Cruz, the supply seems to be increasing rather than diminishing. The wastes of water hyacinths are simply alive with the creatures, and while the tangle of the plants and roots makes fishing for them difficult, these places are becoming more and more the favourite localities for taking the turtles. In open waters they are caught with seines, but among the hyacinths recourse is had to the spear, as nets cannot be used advantageously. On account of the lack of shipping facilities the consumption of the turtle is restricted and largely local. It can, however, be easily transported. The turtles will stand shipment of several days by simply being occasionally doused with cold water, and arrive at their destination in a lively condition. Turtles of twenty-five to thirty pounds weight, sell

Hosted by Google

in southern Vera Cruz towns for a sum equivalent to about 1*s.* 7*d.*; large ones sometimes bring as much as 2*s.* in the local markets. These turtles are fat and fine of flesh, and under careful handling would give a good return to the man who undertakes to ship them either to the markets in the interior of Mexico or to the United States. By arranging shipping boxes provided with a small tank for fresh water, in which the turtles could bathe, they could easily be put on the northern markets in prime condition, and just as good as when taken from the rivers. For shipping purposes only net-caught turtles should be handled, for speared turtles, though the wound may be slight, are liable to spoil, owing to the inflammation of the wounds. There is a small swamp turtle called "pochitoque," which is of extremely fine flesh and flavour. It is found in great numbers in the swamps and lands that are annually overflowed in the State of Tabasco, and is very similar and quite equal to the famous diamond-back turtle. This also could be readily shipped to northern markets. It is not quite so abundant as the river turtle, but would find ready sale at fancy prices in view of the diminishing supply of the diamond back. As it lives a good part of the year on the land the question of shipping would be correspondingly simple, and expenses less than in the case of the water turtles. These land turtles are annually destroyed in enormous numbers by fires, either accidental or intentional, which devastate the lowlands, and tens of thousands of them are left to rot when burned.

THE JAPANESE FRUIT INDUSTRY.

The principal fruits of Japan are persimmons, mikan (mandarines or Japanese oranges), pears, apples, peaches, grapes, strawberries, apricots, water-melons, figs, walnuts, and chestnuts. Apples are very popular in the country, and the history of Japanese-grown apples, as developed in the principal cities, dates back only a few years. Young trees were imported from America and planted in Hokkaido (northern island), and in the northern provinces of Akita, Aomori, and Yamagata. The experiment proved very successful, and about twelve years ago northern apples began to supply Tokyo and other large city markets in Japan. The people in general, however, have not yet learnt to use the apple or any other fruit in their common diet, its principal use being for afternoon tea, or for children, usually to be eaten between meals. Apple jam or other forms of cooked apples are almost unknown among ordinary Japanese families. As a rule apple-growing is considered as an incidental source of income among Japanese farmers. No statistics as to acreage, number of trees planted per acre, varieties, average yield, irrigation, etc., are available. The Oonshiu, or Satsuma, orange is grown in the southern and south-eastern parts of Japan, the northern prefectures and the western coast being too cold. Oranges, according to the American Consul at Kobe, are grown chiefly at an altitude of six hundred to two thousand feet above sea level. A southerly exposure is best for the tree, and the best soil is a sandy loam with gravel about three feet from the surface. The land should be hilly and rolling. The most favourable temperatures range from 36° to 95° F., with an average of 65°. It is uncertain what degree of cold the Satsuma orange can stand without being killed, but at Wakayama, with a temperature of 22°, no trees have been reported killed. Strong gales, especially sea winds in summer, cause the leaves to wither, and are generally considered worse for the trees than cold weather. In the more northerly districts where oranges are grown the trees are sometimes covered with coarse matting in winter. It is impossible to state accurately the age that Oonshiu oranges will attain, as there are no records of the dates of planting of the very old trees. There is a tree about one hundred and fifty years old in Kamomura, Wakayama Prefecture, whose trunk is over four feet in circumference near the roots. A tree at Takatamura, Kumamoto Prefecture, is said to be the oldest in Japan. Up to ten years ago its branches had a spread of sixty feet radius in every direction, but they are now reduced to an east and west diameter of twenty-seven feet, and a north to south measurement of one hundred and eight feet. Roots have grown from the branches of this plant, which lie on the ground. Oranges were formerly grafted on the Yudsu (*Citrus aurantium*), but now the Kikoku (*Citrus fusca*, or *Citrus trifoliata*), which is much hardier, is widely used. Grafting on trees is commonly done without removing them from the ground, but sometimes the trees are dug up, grafted and transplanted. Budding is a new system in Japan, but it is gradually being widely adopted. The Oonshiu orange tree usually grows ten or twelve feet high, covering a space twenty-two or twenty-three feet in diameter. It branches close to the ground, and not being pruned the weight of the fruit causes many branches to lie on the ground. The Japanese prefer a low tree, as the fruit can be picked without ladders and the branches keep the ground cooler and more moist than it would be if exposed to the sun. The recent progress in fruit culture in Japan has been very striking, it being now considered as a far more profitable occupation than ordinary farming, and it is also considered to be superior to the ordinary laborious work of tilling. The result of this is that the better class of farmers are now engaged in it. At one time orchards were found only in places adjacent to large towns, but at present orchards of oranges, peaches, apples, etc., are found in remote places. Hills are now extensively opened up to lay out orchards, and places favourably situated command, in fruit districts, astonishing prices. Generally speaking, apples are grown in Hokkaido and Aomori; peaches near Tokyo and in Okayama; pears in the suburbs of Tokyo, in Saitama, Niigata, Nara, Chiba; grapes in Yamanashi, Tochigi, and Niigata; oranges in Wakayama and in Southern

Hosted by Google

Japan. Persimmons may be said to grow everywhere. Cherry trees are prized more for their flowers, and their fruits are therefore altogether secondary. Foreign cherry trees are cultivated in Yamagata.

EMPIRE NOTES.

Canada and Labour Disputes.—The Canadian Act for dealing with industrial troubles connected with "Public Utilities"—that is mines, railways, engineering, and other large industries—appears to have worked well during the five years in which it has been established. The main principle of the Act is compulsory investigation, with the view of bringing about voluntary conciliation and arbitration. It requires that any cases of dispute arising between an employer and his employees, which may be of sufficient importance to justify State interference, should, before it is allowed to issue in a strike or lock-out, be submitted to a board, which has power to require the attendance of witnesses and to investigate fully the causes of such disputes. The *Official Labour Gazette* of Canada, in reviewing the proceedings under this Act, says that "during the five years the Industrial Disputes Investigations Act has been in operation, 124 applications have been received for the establishment of boards of conciliation, the result of which has been that 110 boards were established, and in the fourteen remaining cases the matters in dispute were adjusted by mutual agreement. In ninety-three out of the 110 cases referred for investigation, the inquiry resulted either in a direct agreement between the parties, or in such an improvement of relations as led to the settlement of the dispute." This is a very satisfactory statement, and may indicate the course that should be adopted in this country. In any case, if investigation can be made prior to a threatened strike or lock-out, it were better than investigation and an attempt at conciliation after the strike or lock-out has been declared. In the former case the chances are that when the causes of the dispute have been ascertained, the parties to it may far more easily be brought together and the differences between them adjusted. The only compulsion used in the Canadian Act applies to the preliminary inquiry. When that is concluded, and the effort at conciliation resulting from it has been made, the further steps that may be taken are left to the parties, who are free then, if they so desire, to carry their dispute to the arbitrament of industrial war, but not till then.

The Cost of Living in Australasia.—Last year the Commonwealth Statistician published a return as to the cost of living for the twelve-monthly period July 1st, 1910 to June 30th, 1911. Copies of small account-books had been distributed among 1,500 householders throughout the Commonwealth, in which provision was made for weekly records to be kept of all receipts and expenditure. Of the 1,500 to whom the books were sent, 212—including 107 with over four members, and 105 with under four members per family—furnished the required particulars. The number of children recorded was 522, or an average of 2·46. New Zealand, desiring to obtain similar information, issued 2,000 books for records to be kept from October 1st, 1910 to September 30th, 1911. Of this number only sixty-nine families—including twenty-six with over four members, and forty-three with under four members —furnished the required particulars. The children numbered 160, or an average of 2·32 per family. From so small a proportion of returns received, no complete statement of the cost of living can be deduced either for the Commonwealth or New Zealand. Nor can a full comparison of the relative cost of living as between the two countries be deduced, as the Australian inquiry included country as well as town workers, while the New Zealand inquiry was for town workers only. Some very useful information has, however, been obtained, which will, doubtless, lead to the creation of a wider public interest in the subject, and to the organisation of a system of inquiry which will secure fuller and more adequate returns. From the particulars recently published by the New Zealand Department of Labour, it appears that the four main items of expenditure dealt with housing, food, clothing, and fuel and light. The returns show that the worker with no family spends very nearly the same sum weekly on food, but saves in rent, clothing, and other items; and at each week-end has a surplus of 1*s.* 9½*d.* Apparently, he buys more luxuries, in the way of food, than his co-worker who has a family, and his average expenditure on clothing is also higher. The family man pays 5*s.* more rent per week, 8¾*d.* more on food, 1*s.* 1¾*d.* on clothing, and 3*s.* 3½*d.* on other items. His fuel and light expenses, however, are relatively lighter to the extent of 1*s.* 4½*d.* per week. This worker, however, has no surplus at the week-end. The figures generally indicate, as may be expected, the favourable position, as far as expenditure is concerned, of the families possessing few, if any, children. The New Zealand returns show, as do the Australian, that the cost of food is by far the most important factor, amounting to nearly 34 per cent. of the total expenditure. Next comes housing, 20·22 per cent.; then clothing, 14·47 per cent.; and fuel and light, 5·20 per cent. In respect to alcoholic liquor, no less than thirty-nine out of the sixty-nine returns received, or 56 per cent., are from teetotal families. The average expenditure per week of the thirty non-teetotal families is 9½*d.*, as compared with the general average for the country of 4*d.* The average weekly expenditure on tobacco and cigars is shown as 7½*d.*; but, excluding twenty-six non-smokers out of the sixty-nine, the average is 1*s.* Six families only gave their expenses as "nil" for "sports and amusements," the average all round being almost 1*s.* per week. Friendly society and trade union contributions were paid by 63 families, an average of 91 per cent. Medical expenses averaged 1*s.* 1*d.* per

Hosted by Google

family; and all, excepting eight families, showed expenditure under this heading. The average expenditure for rates and taxes was *5d.* Many other particulars are given in the report of the New Zealand Department of Labour, as well as a complete table of the prices of commodities, from which it may be seen that the prices of the staple articles of food compare favourably, in some instances very favourably, with those in the United Kingdom.

New Zealand's proposed Honour to Wakefield.—Fifty years ago, Edward Gibbon Wakefield, to whom New Zealand and the Empire owe so much, died in Wellington, and at last the country which he served so well is about to honour his memory. On this subject the *New Zealand Herald* says:—"As yet, no public monument or memorial has been raised to the man who rendered such conspicuous service to the cause of colonisation, and who is rightly regarded as the real founder of the colony of New Zealand. Happily, this reproach will shortly be removed. It is, indeed, remarkable that so great a man should have found such small honour in a State which owes its very being to him. His name is seldom heard, his labours forgotten. He rests in a grave which only the curious know or care to visit. Wakefield, a compound of paradoxes, has achieved the great paradox of life: a success so complete and lasting that the world forgets he ever fought. It is, however, time our national conscience pricked us. No lapse of years can bar the debt we owe to Wakefield, and common gratitude should urge us to make some public acknowledgment of it which will keep his memory fresh among us, and prompt, perhaps, later generations to read the story of a life devoted to the advancement of the public good; for, while Wakefield has a just claim to fame throughout all the Oversea Dominions, he has a special and peculiar title to public recognition in New Zealand." The proposal to honour Wakefield's memory, in the way indicated in this article, will be appreciated by many in England who know something of the work done in the cause of Empire by this remarkable man, and by none more than by Sir Frederick Young, who was his coadjutor in the early days of emigration to New Zealand, and who himself has done a great deal to promote the progress and the unity of the Empire, and still lives to mark the advance of those great Imperial interests for which Wakefield toiled and suffered.

An Australian Motor-car Invention.—By an adaptation of the famous "stump-jump" principle, which has done so much for Australian agriculture, an inventor has made it possible for the motor-car to be used on the roughest of roads and tracks with ease and comfort, and to be run at a high rate of speed. What this will mean to the traveller in the Australian bush only those who know the conditions obtaining in that country can fully appreciate. The inventor is Mr. T. T. Charley, and his invention is known as "Charley's Equipoise Suspension." The body of the new car is made to rest on four vertical spiral springs, one on each short axle that supports each wheel. By this arrangement the shock that a wheel sustains, when it strikes an obstacle of any unevenness in the road, is transmitted to horizontal spiral springs, running fore and aft on the car, and then connected with the vertical spring on the hind wheel. So sensitive is the transmission that almost immediately one wheel strikes the obstruction the other is affected, thus giving the minimum of shock as the wheel lifts, immediately the obstacle is struck or an uneven road is traversed. No shock is, therefore, felt by persons in the car. The tyres used in the construction of the new car are simply iron bands fixed to the rim of the wheel, with a band of solid rubber vulcanised to the outside, about an inch in thickness. These tyres are said to be good for 10,000 miles running, the rubber being used chiefly to deaden the sound. By this arrangement, which can be applied to any ordinary motor-car, the pneumatic tyre is rendered unnecessary. In order to test the value of this remarkable invention, the members of the Australian Northern Railways Commission were invited to take a run in the car, and were driven over a road that would be almost impassable in an ordinary car at a high rate of speed. They went over two deep spoon-drains (the dread of motorists) at about twenty-five miles an hour, yet the shock was scarcely felt by the passengers. The opinion of the members was that the invention has a great future, as it certainly should have, if, on further proof, it be found to accomplish all that is now claimed for it.

The Future of the Dominion of Canada.—In an address recently delivered in this country, the Hon. G. E. Foster, Minister of Trade and Commerce in Canada, made a striking statement as to the present resources and future prospects of the Dominion. Referring to the question of grain production, he stated that last year 180 million bushels of wheat had been harvested in the Prairie Provinces alone, and that to convey this produce to market all their facilities of rail and water had failed to meet the demand for transport. What, then, was the future of Canada likely to be in the development of its transport resources alone, when the whole of the country was made available for cultivation instead of a small percentage, and was brought into productive use? Then as to population, to-day, he said, they had seven millions of people. Last year they received 354,000 immigrants. This year the number would be 400,000. They might, he continued, regard it as a reasonable estimate that for the next fifty years there would be an increase by immigration of at least 500,000 people per year. If to this be added the natural increase, Mr. Foster estimates that in fifty years the population of Canada should be close on 50 million people! He therefore concluded that the coming fifty years would witness a far larger development than the past fifty years had seen. In proof of the present

Hosted by Google

advance of the material prosperity of the Dominion, recent returns show that trade is increasing at the rate of nearly 20 million dollars a month (£4,109,598), while the final results for the past fiscal year show a surplus of about 38 million dollars (£7,808,219) over all ordinary expenditure. It is indeed difficult to estimate what will be the development of a country if its advance in population and trade is maintained on lines proportionate to those of the past few years.

CORRESPONDENCE.

PAPAYA OR PAWPAW.

Referring to the note in the *Journal* of the 2nd inst., on the "Papaya or Pawpaw," by our member, Captain R. C. R. Owen, Governor of the Mongalla Province of the Sudan, I may at once state for his information that its properties of rendering meat tender have been known in India almost from its first introduction there by the Portuguese from South America; and have in our own day been made widely known through the writings of Sir William Henry Sleeman, the Rev. Dr. Francis Mason, and the Rev. Alexander Kyd Nairne; to say nothing of official reporters on the commercial products of India,—of whom Sir George Watt is the head and front of all of us. His great "Dictionary of the Economic Products of India" ought to be placed by the Imperial Government in the hands of every British administrator throughout our tropical and sub-tropical possessions.

In the *Journal* of March 1st last, I dealt only with the etymology of the word "pawpaw," its Cuban name,—? from the *Carib ababi*,—rendered *papayo* by the Portuguese, and *papai* by the people of India—of the plant, the Carica Papaya of Linnæus. Meat of any sort wrapped up in its large castor oil-like leaves [it is a "Passion flower"], or placed beside its fruit, or hung in the shadow of its palm-like head of leaves and fruits, rapidly becomes tender; while the flesh of fowls fed on its seeds seems as if digested alive by them to the mollisity of a *mousse* at the Dieudonné. The fruit cooked is a good substitute for apples—stewed, or as boiled dumplings, or baked pies—and seems to have digestive virtues; the seeds certainly have. They are pungent, with something of an ethereal flavour added; and dried and pounded are an excellent substitute for pepsine; and innocent of all taint of slaughters that must, in consideration of their needlessness, be accounted, each one of them, as foully murderous as the offerings passed through the fires to Moloch.

GEORGE BIRDWOOD.

NOTES ON BOOKS.

ENGLAND'S INDUSTRIAL DEVELOPMENT. By Arthur D. Innes. London: Rivington & Co. 5*s*.

The author states in his preface that it has been his object to provide for the ordinary reader a "concise historical survey of the Development of Industry and Commerce in England," and he may certainly be given the credit of having succeeded. As he begins with the Roman conquest of Britain, and ends with a reference to the industrial difficulties of last year, it cannot be said that his survey lacks completeness. Indeed, he treats his long period of two thousand years with commendable skill, and compresses into the 374 pages of which the book consists a vast amount of information of a sort not to be found in ordinary historical text-books.

His treatment of the subject is throughout that of a student of economics; the scientific and technical side of industrial history is passed over—one hardly likes to say neglected—but where any technical or scientific details are included, they are, so far as can be judged from a cursory perusal of the book, correctly given, and this is something to be thankful for. The work is divided into three parts —"The Middle Ages," "The Mercantile Period," and "The Industrial Era." The first two parts may be looked at as introductory to the third, and give us in a concise but quite interesting shape the economic and commercial history of England down to, say, the American Revolution, or, as we might prefer to date it, the completion of the steam engine. To many readers these first two parts of the book may very probably be the most interesting, and they may be commended to all who care to study other details of the history of their country besides its battles and the adventures of its monarchs. The third part, which deals with modern industrial England from the industrial revolution to the present time, is an excellent and compendious account of the economic, financial, and commercial history of the country during that period. It includes chapters dealing with the Poor Law, Laissez Faire, Free Trade, the Factory Acts, Trade Unions, and other subjects, including the various attempts to regulate and improve industrial conditions by legislation. Perhaps some day somebody will write a history of the influence of science upon industry, and such a work will provide Mr. Innes's excellent treatise with the complement it requires.

GENERAL NOTES.

SCHOOL OF ART WOOD-CARVING.—At the recent National Competition one student of this school was awarded a gold medal, a second received National Book Prizes, while a third was commended.

THE PRODUCTION OF EDIBLE TUBERS IN MEXICO.—The chinchayote is the tuber of a gourdlike plant grown in the State of Guadalajara, whose botanical name is *Sechium edule*. The year-old tubers are boiled and candied, and are sold by street vendors, being very popular among labourers and children. The larger two-year old tubers are sliced and fried for table use. The tubers yield an excellent starch,

Hosted by Google

similar to arrowroot or sago. Above ground the chinchayote is similar to a gourd plant, with a smaller leaf, and the flower develops into a bulbous fruit covered with prickly spines called the chayote. The tubers are the part known as the chinchayote, and these resemble a sweet potato in shape, the colour under the skin being white. Each plant produces ten to thirty tubers, having a total weight of five to thirty pounds, varying with age, as some plants are allowed to grow for two years, producing larger and more numerous tubers. For cultivation the chayotes are sprouted in a moist place, and then planted sometimes three plants together. The planting season, according to the American Consul at Guadalajara, is from February to April, and the plant requires little attention thereafter. The chayotes or fruit are gathered in September or October, and the chinchayotes or tubers mature from October to December, being taken up when they reach the desired size. The shrubs are planted seven to ten feet apart, loose soil that has been used for other crops being the best.

Liquid Fuel for the Navy.—The King has been pleased to approve of the appointment of a Royal Commission to report on the means of supply and storage of liquid fuel in peace and war, and its application to warship engines, whether indirectly or by internal combustion. The following will be the members of the Commission:—Admiral of the Fleet the Lord Fisher of Kilverstone, G.C.B., O.M., G.C.V.O. (Chairman); the Right Hon. George Lambert, M.P.; Sir Boverton Redwood, Bart.; Sir Philip Watts, K.C.B., F.R.S.; Engineer Vice-Admiral Sir Henry John Oram, K.C.B., F.R.S.; Vice Admiral Sir John Rushworth Jellicoe, K.C.B. K.C.V.O.; Sir William Matthews, K.C.M.G.; Sir Thomas Henry Holland, K.C.I.E., F.R.S.; Sir Thomas Edward Thorpe, C.B., F.R.S.; Alexander Gracie, Esq., M.V.O.; Humphrey Owen Jones, Esq., M.A.; and Alfred Fernandez Yarrow, Esq.; Captain Philip Wylie Dumas, C.V.O., R.N.; Engineer-Lieutenant Charles John Hawkes, R.N., and John Harper Narbeth, Esq., M.V.O., Royal Corps of Naval Constructors (joint secretaries).

Commerce of Patras.—The trade of Patras, stimulated by the exceptionally good harvests of the last two years, has been very satisfactory of late. Amongst the principal imports, which include manufactured goods of every description, corn, sugar, etc., salt codfish from Newfoundland takes a prominent place. It is largely consumed by the Greek peasantry. During the two months ending December 31st, 1911, no less than 34,781 quintals (68,466 cwts.) of this commodity were landed at Patras. Two lines of Liverpool steamers touch at Patras regularly every fortnight bringing a quantity of English goods, which are forwarded from thence to other towns inland. The principal exports from Patras consist of currants, olive oil and preserved olives, dried figs, wine and tobacco, which is extensively grown in the district; this is chiefly exported to Germany and Holland.

Market-gardening in Lombardy. — Some recently published official statistics give some interesting information respecting market-gardening in the Province of Milan. The total area cultivated for the supply of vegetables in this district is 1,059 hectares (2,615 English acres), of which 505 hectares (1,247 acres) are situated in the immediate vicinity of Milan. The total gross value of the produce of these 1,059 hectares is estimated at 6,885,000 lire (£275,000) annually. The following is the average yield per hectare and in acres of some of the principal crops:—

	Per hectare.	Per English acre.
Cabbages	35,000	14,175
Celery	110,000	44,550
Small marrows	50,000	20,250
Radishes (no. of bunches containing 18 in each)	12,000	4,860
Lettuces and small salads	90,000	36,450
	quintals	cwts.
Tomatoes	280	551
Potatoes	135	266
Asparagus	45	88
Carrots	100	197
Beetroot	200	394
Turnips	160	315
Spinach	60	118
Onions	125	246
French beans	40	79

The average gross yield is valued at 9,000 lire per hectare (£145 8*s.* per acre), in the neighbourhood of Milan, per annum; at 4,000 lire (£64 8*s.*) near other towns in the province, and at 2,500 lire per hectare (£40 9*s.* 7*d.* per acre) in the rural districts.

Production of Wine in Turkey.—The production of wine in Turkey is an industry capable of great development, especially in Syria, Palestine, Smyrna and Salonica. The total quantity of wine made in 1910 is estimated at 100,000 tons (about 220,000,000 gallons), the greater part of which was consumed in the country and in Egypt. A considerable quantity of red and white wines were also exported to Germany, France and America. Wine is also one of the principal articles of export from Jerusalem to the United States.

Italian Trade at Stavanger.—The trade between Italy and Stavanger does not as yet appear to be of much importance, but according to the report of the Italian Consul at that port it shows a tendency to increase. This is due to the establishment of a direct line of steamers (Norwegian) between Stavanger and Italy. The exports to Italy last year consisted principally of 1,250 cases of sardines, 6,903 deal boards for making packing-cases, and about 1,167 tons of old iron. On the other hand, Italian produce seems to be more in demand, and included 520,550 kilogs (1,147,812 lbs.) preserved tomatoes, 475,800 kilogs (1,049,134 lbs.) olive oil, twelve casks of wine, 236 bales of hemp, 457 slabs of marble, lemons, almonds, etc.

No. 3,117. VOL. LX.

FRIDAY, AUGUST 16, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICE.

EXAMINATIONS.

The results of the Elementary Examinations (Stage I.) have now been issued. The results of the Intermediate Examinations (Stage II.) were published on July 15th, and the results of the Advanced Examinations (Stage III.) on June 15th.

The programme for 1913, containing the previous year's papers and the examiners' reports on the work done, will be published in September.

The time-table for 1913 is as follows:—

ROYAL SOCIETY OF ARTS EXAMINATIONS, 1913.

	Monday, April 7 (7–10 p.m.).	Tuesday, April 8 (7–10 p.m.).	Wednesday, April 9 (7–10 p.m.).	Thursday, April 10 (7–10 p.m.).	Friday, April 11 (7–10 p.m.).
Advanced Stage.	Book-keeping. Précis-writing. Economics. Danish and Norwegian.	Arithmetic. Commercial Law. German. Italian. Spanish.	French. Commercial History and Geography. Typewriting (7.30 to 10 p.m.).	Accounting and Banking. Shorthand (140 and 120 words per minute) (7.15 to 10 p.m.).	English. Portuguese. Russian. Swedish. Chinese. Japanese. Hindustani.
Intermediate Stage.	Typewriting (7.30 to 10 p.m.). French. Danish and Norwegian. Commercial History and Geography.	Book-keeping. Précis-writing.	English. Economics. Spanish. Commercial Correspondence and Business Training.	Arithmetic. German. Portuguese. Italian. Russian. Chinese. Japanese. Hindustani.	Swedish. Shorthand (100 and 80 words per minute) (7.15 to 10 p.m.).
Elementary Stage.	Handwriting and Correspondence. French.	Commercial Geography. Typewriting (7.30 to 10 p.m.).	Book-keeping. Spanish.	Shorthand (50 words per minute) (7.15 to 10 p.m.).	Arithmetic. German. Italian.
Music.		Harmony.	Rudiments of Music (7 to 9 p.m.).		

Hosted by Google

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

THE MATERIALS AND METHODS OF DECORATIVE PAINTING.

By Noel Heaton, B.Sc., F.C.S.

Lecture III.—Delivered April 1st, 1912.

Oil and Tempera Painting.

I pass on to-night to the consideration of the various methods of painting in which the pigments are not incorporated with the ground as in fresco, but fixed to it by means of a vehicle or medium. All such substances are organic in nature—that is to say, they are complex compounds of carbon produced by animal or vegetable growth, and, as we have already seen, the substances available for this purpose vary in their nature and properties, different methods of painting being based on the properties of different classes of compound.

First of all, we have substances such as gum, which are freely soluble in water, and which can be used as a vehicle in the form of a solution, the pigments being mixed with this in painting and fixed to the surface by the film of original gum left on evaporation of the water. Such a water-colour painting is, however, subject to destruction by moisture, and is quite out of the question for permanent painting.

Tempera Painting.

The first process we have to consider which fulfils the necessary condition of permanency is tempera, in which the binding agent is mixed with water for purposes of application, but has this difference as compared with distemper, that it becomes insoluble after drying, the painting being thus rendered permanent.

This result is generally obtained by the use of an *emulsion*, which may be described as a false solution, being only apparently soluble in water, consisting, in reality, of a substance insoluble in water but rendered capable of mixing with it by being broken up into minute particles, which remain in suspension. An oil, for example, can be emulsified by shaking it up vigorously in water in which some substance of the nature of glue is dissolved. The most familiar example of such an emulsion is milk, which has been used from time immemorial as an addition to size in distemper painting. The emulsion generally used in tempera painting is yolk of egg, which consists of globules of oil suspended in a solution of albumen. This is freely mixable with water, but although on drying the particles of pigment are at first only held by the albumen, and are consequently removable by washing, after a time the oil hardens (by a process to be described shortly), and binds the pigments more firmly, the painting becoming practically waterproof.

This medium was, as we have seen, largely employed in mediæval times for decorative painting.

In working in tempera it is decidedly best to paint on an absorbent ground such as plaster, the medium then sinking into the substance of the ground and keying the painting well on to it, instead of remaining on the surface, as is the case if a non-absorbent ground is used. It is true that it is more difficult to paint on an absorbent ground; but it can be done, and if durability is desired the difficulty must be surmounted.

Tempera painting can either be executed on the wall itself or on a separate ground, such as prepared panel, canvas or paper; in the case of the former the plaster should be plaster of Paris for preference, as this is not attacked by the sulphuric acid present in the air. If a painting is executed on lime plaster it is important to see that the process of conversion of the lime into carbonate of lime has completely taken place, as the caustic lime is destructive to the organic medium.

During recent years tempera painting has been widely used in ordinary house decoration, many mediums having been introduced for the purpose under the name of "washable distempers." Such mediums are, of course, proprietary articles, and one is not familiar with their exact composition, but, broadly speaking, they may be described as emulsions, similar in character to yolk of egg, but consisting of a vegetable oil such as linseed oil, suspended in a solution of size. The best of these products are excellent mediums, and there is no reason why they should not be employed for decorative painting on a large scale.

Amongst these washable distempers we find also in extensive use another medium which is essentially different in properties. This is not an emulsion at all, but depends on a different reaction for its binding properties. This is the albumen extracted from milk, used in mediæval times under the name of "cheese-glue," and generally known as casein. When milk is "de-emulsified" or "separated," to obtain the cream, the casein remains in the "skim-milk," from which it is obtained by the addition of acid which "curdles" the milk—that is, pre-

Hosted by Google

cipitates the casein as a solid insoluble in water. In making cheese (which consists largely of casein) an organic acid (rennet) is used, but in preparing casein for industrial use the skim-milk is heated with hydrochloric acid, and the casein is thus prepared in immense quantities in the form of a granular powder. Casein, although itself insoluble in water, if treated with an alkali, such as soda, potash, ammonia or lime, forms compounds which are soluble in water. The compounds with soda and potash are of no particular advantage, but in the case of ammonia and lime the production of a tempera medium is rendered possible. If a painting is executed with such a solution as a medium it is rendered insoluble and waterproof on drying by the evaporation of the ammonia in the one case and the gradual conversion of the lime into carbonate of lime in the other, thus setting the original casein as an insoluble binding agent. The former method is somewhat objectionable, but the latter is perfectly practicable, and is, in fact, largely employed in the production of "washable distempers." For decorative painting, however, one is inclined to suggest the use of baryta water instead of slaked lime as the dissolving agent, as it is much stronger and absorbs carbon dioxide more rapidly than lime, so that the painting is rendered more quickly insoluble.

Casein painting, it will be noticed, has the great advantage over ordinary egg tempera that it can be employed on a freshly prepared lime-plaster with advantage; in cases where a newly-executed fresco painting requires a little subsequent alteration, "a secco," therefore, this is eminently the process to adopt. It must be remembered, on the other hand, that in casein painting one is limited as regards pigments to those that can be used in fresco painting, whereas in ordinary egg tempera many additional pigments, such as the more permanent colours in Classes IV. and V., are admissible.

All tempera paintings are liable to attack by moulds if allowed to become damp, which causes more or less rapid disintegration of the medium; but this may be to a large extent prevented, and the medium, moreover, rendered far harder and more insoluble by treatment, after the painting has been executed some days, with a 10 per cent. solution of formic aldehyde (formalin) applied over the whole surface with a soft brush, or by means of a spray diffuser.

Oil Painting.

We now come to the oil medium, which is quite different in nature from anything previously considered. In ordinary oil painting, of course, the pigments are merely ground in pure oil, the paint so prepared gradually hardening on exposure to the air, but remaining in a plastic condition for days, allowing the painting to be altered and repainted in a way that is impossible with any other medium. Moreover, the paints will keep indefinitely if preserved out of contact with air, so that they are generally prepared wholesale, and perhaps pass through two or three hands before they reach the artist, who very often is entirely ignorant of their nature and preparation.

These facilities are an undoubted advantage in many ways, although they are not without compensating disadvantages, which, however, it would be outside our present purpose to discuss. Oil painting is, however, the method of painting in general use at the present time, and the nature and technology of the method have been frequently explained, so that it is unnecessary to deal with it fully. I will merely remind you of the most important points concerning the nature of the medium. In the first place it must be understood that what is termed the "drying" of oil is essentially different in nature from the drying of distemper. For instance, the oil does not evaporate; on the contrary, there is more of it present after drying than before, for the process is really one of oxidation—that is to say, the oil, when exposed to the air, absorbs oxygen, and by so doing is gradually changed from a liquid to an elastic solid substance similar in nature to india-rubber. This peculiar property of "drying" on exposure to air is not a property common to all oils, but only to a few of vegetable origin, the most important of which are linseed oil, poppy oil, walnut oil, and tung oil. The first is the oil generally used in house painting, but the second, and sometimes the third, are used in the preparation of artists' colours, as they are paler and sometimes slower in drying.

It is important to understand clearly the nature of the drying action, because it is this very property which limits the durability of an oil painting. The process of combination with oxygen does not cease when the change to the solid state has been effected, but continues at a slower rate, with the result that the film of dried oil from being soft and elastic becomes harder and more brilliant, until finally it disintegrates entirely. The rapidity with which the change takes place, however, varies enormously according to the conditions of exposure. If an oil painting is

Hosted by Google

directly exposed to fresh air and bright sunshine it will perish quite quickly, and more quickly the more fresh air and sunshine it gets, because under such conditions the oxidation is more rapid. When protected from the direct action of the atmosphere, however, by being placed indoors, and more particularly if sealed by a coating of varnish, this action takes place very slowly, and a film of oil paint is remarkably durable, provided that it is properly prepared and properly applied, so as to avoid any tendency to cracking and other defects.

The oil film, however, inevitably suffers this change sooner or later, becoming hard and brittle; also, as a result of this change, organic bodies of an acid character are produced which attack and weaken the ground to which the painting is attached. The oil film also darkens in colour considerably, as a result of exposure, with the result that the brilliancy of the painting is reduced and often entirely obscured.

There is a further cause of destruction in the case of oil painting, which should not be of any moment in the case of paintings executed on a ground such as canvas or panel, but becomes of importance in connection with its application to mural painting, and that is that whilst a drying oil is practically unaffected by acids, it is rapidly decomposed by alkalies, such as soda, potash or lime. This is due to a chemical reaction generally known as "saponification," the general nature of which is indicated in the diagram:—

$$\text{Vegetable Oil}\begin{cases}\overbrace{\text{Organic Acid}\qquad \text{Alkali } (\textit{Soda, Potash or Lime})}^{\text{Soap}}\\ \text{Glycerine}\end{cases}$$

The oil is a compound of glycerine, with a complex organic acid, with which the alkali combines to form the substance soluble in water familiar to us as soap, setting the glycerine free. Now glycerine, as is well known, is very strongly hygroscopic, and the result of this action is, therefore, that the film of paint gradually dissolves away entirely.

Now we have seen in our discussion of the nature of fresco painting that a freshly-plastered wall contains a large amount of caustic lime, which is gradually converted into carbonate of lime on exposure to the air. This caustic lime has all the properties of an alkali, and although, as we have noticed, the conversion commences immediately the plaster is laid on the surface, the amount of carbon dioxide in the air is small and the conversion of the entire substance of the plaster is a very lengthy matter indeed—in fact, in examining the ancient frescoes of Knossos, where a very great thickness of lime-plaster was employed, I found that a minute trace of caustic lime was still present in those portions furthest from the surface, after over 3,000 years' exposure.

Bearing this fact in mind, it is clear that if oil painting is to be applied to a lime-plaster wall, care should be taken to see that it is not only perfectly dry, but free from all traces of caustic lime. In the case of gypsum plasters, such as plaster of Paris, Keene's cement, Siraphite, and so forth, these remarks do not apply, as the setting is an entirely different process, no free lime being present. Dryness is, however, of importance even in this case, for if moisture be present when the paint is applied, it will, of course, tend to evaporate, causing blisters and breaking the oil film.

But, under any circumstances, an oil paint such as is used for pictures, although delightful to work with, produces a surface which is eminently unsuitable for decorative paintings; and it is necessary, therefore, if oil is to be used at all, to modify its composition. Many works have been executed with a medium consisting of oil to which a certain amount of paraffin-wax has been added, but although this produces a matt surface and the immediate result is so far satisfactory, the ultimate gain is questionable, as the medium is in a condition of instability, the wax tending to crystallise out from the oil. Moreover, such a medium is similar in its working qualities to oil paint, and the inevitable tendency is to work with it in oil technique, producing impasto effects which are objectionable in decorative paintings, both on the score of design and durability.

Oil Tempera.

The alternative method of producing a soft matt surface by reducing the oil to a minimum, merely sufficient to fasten the pigments to the ground, by diluting it largely with a volatile solvent such as turpentine, appeals to me far more strongly on technical grounds. With such a medium, flat painting is inevitable, and both in the result and in the working it resembles tempera rather than oil; for which reason I have ventured to call it oil tempera. But it must be remembered that in such a process the pigments are very loosely held—in fact, we find that every endeavour to produce the quality of surface we seek by means of an organic medium leads to practically the same point; distemper, tempera and oil tempera all produce a beautiful

Hosted by Google

quality of surface, but one which is little calculated to resist the ravages of our modern polluted atmosphere. As with fresco painting, some protection of the surface, to enable the painting to be cleansed without detriment, is essential.

We may dismiss the question of varnishes in a few words, because although, if properly constructed and applied, they are efficient from the point of view of protecting, they inevitably destroy that quality of surface we have been seeking to produce.

There can be little doubt that the most durable method of painting possible with an organic medium is that employed in coach-painting—executing the painting in oil tempera, or even water-colour, and then sealing from every chance of atmospheric action by successive coats of varnish, each coat being carefully rubbed down before the next is applied, so that ultimately an almost mirror-like surface is produced, hard, elastic, and capable of being washed without injury.

There is no reason why such a process should not be employed in the execution of pictures; in fact, I am inclined to think that the success of Van Eyck in producing permanent pictures —which has been a constant puzzle to later generations— is to be attributed more to some such painstaking method of working than to any secret medium. Such a method is, however, inadmissible for decorative painting; but I would say this in passing, that I would prefer even this, if the only alternative were absolute surrender to the difficulties encountered: acknowledgment of defeat by the absurdity of placing mural decorations under plate-glass.

ENCAUSTIC PRESERVATION.

But fortunately another method of treatment is open to us. We have so far omitted all reference to the process of encaustic painting, the medium of which consists of melted wax. Attempts have been made to revive this method as introduced by the late Greeks and early Romans, mixing the pigments with melted wax and painting with this as a medium. Painting of a very durable character and pleasing quality can be obtained in this way, but the execution of a painting on a large scale by this process would be attended by very great difficulty, for—in this country at any rate—it would be no easy matter to maintain a large wall surface at a sufficiently high temperature to prevent the wax solidifying immediately on being applied to it. But all this difficulty can be obviated by following the hint given us by

METHOD	VEHICLE or Medium	FIXING PROCESS	DURABILITY. Moisture	Acids	Alkali	Dirt
WATER COLOUR	Solution of GUM in Water	Drying	Destroyed	Destroyed	Destroyed	Absorbed
DISTEMPER	Solution of GLUE in Water	Drying	Destroyed	Destroyed	Destroyed	Absorbed
TEMPERA	EMULSION of Oil	Drying + Oxidation	Damaged	Destroyed	Destroyed	Absorbed

some of the craftsmen of Pompeii, and combining the advantages of the two methods by executing the painting at leisure in tempera or oil tempera, and subsequently impregnating it with wax, by the method we have already found to solve the same difficulty as regards durability in connection with fresco painting.

And that brings me to the end of our survey of the methods of painting available, and in conclusion I now put together, in the form of a table, the main facts concerning the relative advantages of each process, leaving you to decide between them in the execution of your work, as circumstances may dictate, after having pointed out their respective limitations and difficulties.

May I, however, add a few more words respecting the earnest conviction I have already expressed that artists who desire to produce immortal works under present conditions must of necessity pay some attention to such technical principles? I do not wish to suggest, as some have thought, that I am in favour of the artist attempting to become a chemist as well, but each succeeding year confirms me in the views I ventured to put before this Society on a previous occasion, and which I would here like to repeat:

"The artist cannot be expected to prepare all his materials, as some would have him do; nor do I think he would be much better off if he did. Let us frankly realise that whatever may have been the case in the past—and I doubt myself whether this ever was the case—such a thing is impossible under modern conditions of life.

"There must be two sets of workers—the artists and those who work for them; but these two must work together to the same end if the best results are to be achieved; and to render this possible each must understand and appreciate the aims, the problems and the difficulties of the other. There must, in fact, be co-operation between science and art. And I would say, further, that to my thinking the real function of technical education, as far as concerns such crafts, is to bring about this understanding—to teach the practical craftsman the fundamental principles on which his work is based, which he only learns by long and painful experience in his studio."

I have done what I can to put these views into practice, and I must now take my leave, hoping that I have convinced you of their soundness. If so, I trust that you will study such matters further for yourselves in the daily execution of your work.

USE OF REINFORCED-CONCRETE FOR HORTICULTURAL PURPOSES.

Reinforced-concrete is coming into use for the construction of the frames for forcing by French market-gardeners. The cost of the wood for replacing the sides of these frames, which are so extensively used in French gardening for growing early vegetables, is always a serious item in the expenditure. The damp heat generated by the fermentation of the manure soon causes decay to set in, so that frames made of wood rarely last more than three seasons. The cost of the timber required for renewing a 3-light frame, which usually measures about 12 ft. long by 3 ft. 6 ins. wide, may be estimated at not less than 10*s.*, or at the rate of 3*s.* 4*d.* per annum. On the other hand, panels or sides made of reinforced-concrete are practically indestructible, and their first cost should not exceed 7*s.* to 8*s.*

The front and back panels for a 3-light frame should be 12 ft. to 13 ft. in length and 9 ins. and 11 ins. in height respectively. The two sides, which are 3 ft. 6 ins. long, are 9 ins. high at one end and 11 inches at the other, and can be readily made by an intelligent gardener or handyman. The mould, which consists simply of a smoothly-planed board and two strips of wood 1¾ in. thick for sides, is filled with concrete, well rammed, made of slow-setting Portland cement, in the proportion of one of cement to six of well-washed sharp sand and fine ballast. The panels, which must be reinforced by a trellis-work of ¼ in. round embedded in the concrete, should be 1¾ in. in thickness when finished. Iron rings must be provided at both ends, placed so as to receive iron pins to keep the four panels together and so form the frame.

Water-troughs and tanks, as well as posts for fencing, are now largely being made of reinforced-concrete.

SOYA BEAN PRODUCTION IN MANCHURIA.

A very exhaustive report on the production of the soya bean in Manchuria and its introduction into Europe has lately been published by the Chamber of Commerce at Trieste.

Until quite recently the oil extracted from the soya bean was practically unknown on the markets of Europe. Now it is taking the place of cotton-seed and other vegetable oils for many purposes. This oil, exported to Europe for the first time about three years ago, made a great stir in the trade, and its excellent qualities were soon recognised in Holland, England, and Germany. Since 1909 the demand for this product shows no signs of abating, and Russia and Denmark have since entered the field as customers, whilst Germany and the United States have shown their appreciation of the bean by abolishing the import duty.

Hosted by Google

For many years Japan was almost the only foreign customer for this Manchurian product, which from time immemorial has been one of the principal articles of food for the inhabitants of those regions. The chief supply was shipped at Newchanwang, where the trade was entirely in the hands of foreign merchants—chiefly English—established there and their Chinese agents resident up country.

The war between Japan and Russia suddenly changed these conditions, and at the conclusion of peace between the two countries the Japanese became masters of the situation, and managed to divert all the trade to Dalny (now Dairen), the capital of the Kwantung Peninsula. This move was greatly faciliated by the fact that the control of the railways as well as the port of Dalny had passed into their hands.

It was, therefore, an easy matter for them to establish a flourishing trade in Manchuria for the soya bean and its products in exchange for Japanese goods. In this way the Japanese not only succeeded for a time in monopolising the entire export and import trade of the two countries, but even found a market for the product in Europe. This state of things, however, was not of long duration; the example set by the Japanese was soon followed by most of the foreign merchants resident in the country, with such favourable results that the trade is no longer entirely in Japanese hands.

In 1909 the total quantity of soya seed exported from Manchuria amounted to 14,438,049 pikuls* (859,408 English tons), to the value of 32,781,161 Haikwan taels† (£4,097,645), as compared with 4,769,769 pikuls (283,910 tons), to the value of 9,085,379 Haikwan taels (£1,135,672), during the previous year.

The following show the values of the seed exported to various countries during 1909:—

Japan	£749,942
Hong-Kong	521,619
Russia	1,535,920
England	739,050
Australia	51

During the same year the total quantity of bean cake exported from Manchuria amounted to 10,088,359 pikuls (600,498 tons), to the value of 19,247,633 Haikwan taels (£2,408,954), as compared with 7,830,129 pikuls (466,080 tons), to the value of 14,200,839 Haikwan taels (£1,775,105), in 1908. The value of this cake exported in 1909 to some of the principal countries was as follows:—

Japan	£2,456,170
Russia	46,185
Germany	4,262
England	2,109

The exports of the bean from Manchuria in 1910 is estimated at upwards of one million tons, to the value of 25 million dollars (gold), or about 2½ millions sterling.*

In 1909 most of the seed exported to Europe was shipped to England, principally to Hull, where the oil was extracted. The manufactured oil and its residue (bean cake) was sent thence to France, Belgium, Holland, Germany, and Denmark. The following year (1910), however, these countries commenced to import the raw material direct from the East, and to extract the oil themselves.

In 1910 considerable difficulties arose, principally on account of the terrible plague which broke out in Manchuria, and in consequence shippers found it impossible to fulfil their engagements, causing thereby serious losses.

Since then the demand for soya in Europe has steadily increased. Several German firms have established themselves at Dairen and are engaged in shipping this product to Germany, and by means of the steamers of the Hamburg-Amerika line, which call at Dairen and Vladivostock, the transport to Germany is greatly facilitated.

The United States seem about to enter the field as a large buyer, and the admission of the seed and the bean cake duty free will no doubt open the way to establish an immense trade to the Pacific Coast.

The rude methods employed hitherto by the natives for extracting the oil are being replaced by up-to-date processes. An oil factory, fully equipped with modern machinery, was established a few years ago at Dairen by a Japanese firm, with an output of upwards of 12,000 tons of oil in 1910 as compared with 8,000 tons during the previous year.

The yield of oil from the soya bean varies between 13·2 and 22·4 per cent.

In consequence of the great commercial value of the product, experiments are being made in many places to introduce the cultivation of the plant. Good results are reported from Burma, Assam, and in the hilly districts at the foot of the Himalayas, as well as in Ceylon.

The Germans are also endeavouring to introduce the culture of the soya plant in their colonies on the West Coast of Africa.

The great commercial value of this oil cannot be overrated. It is largely used for soap-making; in Germany it is also used in the manufacture of margarine; in France and elsewhere, for preserving articles of food, as sardines, etc., for making sauces, and many other uses.

For the manufacture of paints and varnishes it is also found invaluable, replacing with advantage the more costly linseed and other oils.

As a substitute for india-rubber,† by the treatment of this oil by processes patented by Dr. F. Gosset in Sweden and Dr. A. Sauer in Germany, there may be eventually a large field for the further development of the soya bean industry all over the world.

* Pikul = 133⅓ English pounds avoirdupois.

† Haikwan tael = about 2*s.* 6*d.* English currency.

* The Chinese dollar = about 2*s.* English currency.

THE JAPANESE PAPER INDUSTRY.

Next to cotton-spinning, the production of paper is Japan's greatest industry. Centuries before Western people learned to manufacture paper from rags, the industry was being carried on in China and paper made from actual fibres. From China this art was carried to Europe through Central Asia by the Arabs. It is true that the Egyptians are considered to have been the first paper-makers, but their papyrus was not real paper, but merely the peeled bark of reeds growing on the banks of the Nile. The material for making paper first employed by the Chinese was the so-called paper mulberry bush (*Broussonetia papyrifera*), which is known as "kozu" in Japan. Besides this, the Japanese use the "ganpi," which grows in the mountains of Shikoku, a large island south-west of Kobe, and in the central part of the main island. The Prefectures of Kochi, Ehime, and Kogawa, on Shikoku, and Gifu on the main island, north of the city of Nagoya, lead in paper production. Another plant of no less importance as a material for pulp is the "mitsumata." The value of the annual production of Japanese machine-equipped mills is about £1,600,000, and that of hand-mills reaches £1,900,000. Although native paper has been made from ancient times, it was not until 1872 that the manufacture of European paper was commenced. In that year the Oji paper-mill was established, which uses rice, straw, rags, and waste paper. Soon afterwards factories were established in other parts of the country. After the Saigo rebellion in 1877, a great demand was created for European paper by the rapid adoption of printing in Japan. Whereas native paper is manufactured mainly with hand machines in rural districts affording an abundant supply of pulp, European paper is manufactured in large cities like Tokio, Osaka, and Kobe. Hand-made paper is produced principally by farmers as a secondary occupation, which they can pursue in seasons when there is nothing to be done in the fields. There are no less than 60,000 families engaged in this industry, according to the American representative at Tokio. Japan has been quick in utilising to the utmost its assets in bringing the manufacture of hand-made paper to a high modern standard. In the districts where this paper is made there are experiment bureaus equipped with up-to-date instruments and apparatus for testing and selecting the various kinds of raw material, not only the indigenous plants, but also imported fibres. Co-operation is the secret of the success of the hand-made paper industry in Japan. In every manufacturing district there are guilds which supply the farmers with raw materials and find markets for their product. Experiments have proved that imported wood-fibre may be substituted without detriment in certain kinds of paper for the high-priced native fibres. While Japan exports £406,000 worth of paper annually, it imports £800,000 worth from abroad. The value of the annual consumption of paper in the country amounts to £4,000,000. The domestic production of the better grades of paper is at a comparative disadvantage, owing to the high price of native pulp, the great cost of machinery, and the lack of skill and experience on the part of the operatives. The acquisition from Russia of the island of Sakhalin has furnished a new domestic supply of wood-pulp. This has somewhat lowered the cost of raw materials. A large pulp factory has also recently been established at Shiraoi, on the island of Hokushu.

THE CHILEAN NITRATE INDUSTRY.

Chile has three great productive zones, in some ways quite distinct from each other. In the extreme south, adjacent to the Strait of Magellan, is a newly developing region well suited for sheep and pastoral industries, but showing also mineral possibilities. Its natural product, however, is an abundance of woods, such as pine, where may be found one of the few districts in South America from which building material of this character can be taken. The central part of Chile possesses the famous Central Valley. Here all the products of the temperate zone, and most of those of a sub-tropical climate, grow luxuriantly, and it is by far the most densely populated and highly cultivated part of the Republic. In the north lies the third zone, which appears to be barren, sterile, and worthless, but which in reality, by reason of the nitrate found there, has been the source of much of the wealth of the country. The nitrate fields exported in 1830, the first year of the industry, only about 85,000 quintals (quintal = 220·4 lbs.) of crude material; in 1911 the export amounted to over 53,000,000 quintals, and, according to the International Union of American Republics, there is a visible supply of the nitrate mineral, allowing for increased consumption, for at least the next fifty years.

The nitrate or saltpetre zone embraces an area in the north of Chile of about four hundred and fifty miles from one end to the other. The deposits of the mineral do not lie close to the coast, but are separated from the sea by a district varying from 3,600 to 13,000 feet, in a barren and waterless plain. The climate in this region is delightful, but vegetation is absent, although nitrate forms one of the chief food ingredients of all plant life. Many well-known Chilean ports are on this strip of coast—Pisagua, Junin, Iquique, Antofagasta, Taltal, Caldera—from which the shipment of nitrate is almost the sole business. Saltpetre, or nitrate of soda, is found mixed with other substances. The beds contain four layers of material, the next lowest being that of the nitrate itself. Above this are the "chuca" on the surface, which is nothing more than the accumulation of ages; the "costra" beneath, a harder and older mass, but still somewhat worthless débris; the "caliche," the real nitrate of soda, and finally the stratum of bed-rock called "gova." To obtain the nitrate, a shaft is sunk to the gova, upon which powder is

Hosted by Google

placed and exploded. The overlying mass is thrown up and the caliche containing the nitrate is scattered on the ground. This is then collected and taken to the refining works called "oficinas," for preparation into refined and almost pure nitrate of soda, ready for export. In the oficinas, machinery of the very best pattern is used, and the methods of refining are according to the best researches of industrial chemistry. The consumption of nitrate by the principal countries is as follows:—Great Britain takes about 40 per cent., Germany and the United States each about 20 per cent., France about 10 per cent., and the remainder goes elsewhere, even to such far-away places as Egyyt, Japan, the Hawaiian Islands, and Australia. Chile derives a noticeable part of its income from the export tax on nitrate.

IMPORTS OF WINE IN GERMANY.

The quantity of foreign red wine imported by Germany, for mixing with that of native growth (*vins de coupage*), appears to have fallen off of late years. According to the report of an Italian expert, resident in Berlin, this decrease has been particularly noticeable during the first six months of last year, when only 28,200 hectolitres (620,400 gallons) of wine for that purpose were imported, as compared with 46,286 hectolitres (1,018,292 gallons) during the corresponding period in 1910.

This falling-off is attributed to the shortage in production of this class of wine in Germany, and its high price both at home and abroad. In consequence of this, many of the principal wine makers and merchants in Germany now find it more profitable to import table wines in preference to those for mixing (*coupage*) as was formerly the practice.

The following shows the quantities of this latter class of wine which were imported during 1909 and 1910, and the countries in which they were produced:—

	1909. Hectolitres.	1910. Hectolitres.
Spain	47,830	39,628
Italy	7,804	11,650
Greece	4,058	9,088
France and Algeria	16,330	3,934
Portugal	..	2,226
Austria-Hungary	337	516
Turkey	736	505
Total	77,095	67,547
Gallons	1,696,090	1,486,034

THE SPANISH CORK INDUSTRY.

The cork tree is a species of oak whose outer bark, which is the commercial cork or "corkwood," is first stripped when the tree has a circumference of about sixteen inches, and thereafter regularly every nine or ten years throughout the life of the tree. The best bark, commercially speaking, is produced when the cork tree is fifty to one hundred years old. Stripping the bark, which is usually done during the summer months, is necessarily a rather delicate operation, as great care must be taken not to wound the tree. In many parts of Spain cutting is done by a hatchet, which perforates the bark in complete circles at the base of the tree, and at the lowest fork of the branches. This cylinder-like coat, by a downward slash, is then generally loosened from the inner bark of the tree, and is removed by the aid of a wooden wedge. The same treatment is accorded such larger branches as will yield bark at least half an inch in thickness. The bark taken from the tree trunk sometimes measures more than two inches in thickness, and the total yield of the tree occasionally reaches 500 pounds, though this yield varies enormously from fifty pounds upward, in accordance with the age and size of the tree. After having been stripped, the bark is generally left for a few days to dry. It is then weighed and taken to the boiling station. The simple boiling process makes the bark soft and flexible, and, quite as important, renders easy the scraping off of the woody weather-hardened outer coating which is commercially useless. Occasionally the boiling station is located near the cork forest; in other instances at the shipping port, where the cork factories are situated. At these factories the bark is sorted very carefully, according to quality and thickness, and is then—if for sale as raw corkwood—baled for shipment. The United States Consul at Seville says that by far the greater quantity of the cork yield of Andalusia is exported in the unworked state to England, Germany, Austria, and Belgium, as well as to the United States. An American firm has a branch house at Seville, from which it ships to its home factory a very large quantity of the "corkwood" to be manufactured into articles of commerce. Other local factories produce for domestic and export purposes a relatively small number of manufactured articles, although with the installation of machinery the output is gradually widening in scope and increasing in quantity. In the manufacture of these articles there is a very great amount of unavoidable waste, which is largely exported in the form of cork shavings for use in making linoleum and other by-products of cork. Of all the uses to which corkwood is now put the manufacture of corks themselves still remains pre-eminent. Formerly corks were made almost entirely by manual labour; the workers cut the bark into small squares, from which they whittled out each cork by hand. At the present time this method is still employed in the very small and unimportant "home" factories, where the family

Hosted by Google

constitutes the working force, but the larger local establishments use very satisfactory machinery for the production of corks and discs. One local factory, to supply the export demand for the typical "hand-made cork" (an almost square cork with rounded corners), has invented and installed a simple-moving blade machine, worked by hand. This combines speed with accuracy, and turns out the desired "hand-made" type of cork. The manufacture of a cork is an interesting process when watched from the beginning. Before use at the factory the cork bark in loose bales is boiled for half an hour to render it pliant; upon drying it is sorted into at least ten grades of differing quality and thickness. This sorting is most important, if waste is to be reduced to a minimum, for corks are cut from the bark transversely, and are hence limited in their diameter (rather than in their length, as might at first be supposed) by the thickness of the bark. After sorting, the sheets of bark are cut into strips and squares, according to the length of the cork desired. Next the cork itself is carved out of the small square block, polished by a sand-papering machine, washed, sorted, and disinfected. The corks are counted by an ingenious French machine, and shipped in sacks of strong burlap, containing generally from 100 to 150 pounds. Cork discs, for use in lining metal stoppers, are fast becoming an important article of trade in the cork industry. In their manufacture simple machinery is employed, worked in some factories by an electric motor. Among the other articles in the manufacture of which cork is increasingly used are life preservers, cigarette tips, instrument handles, polishing wheels, carburetter floats for automobiles, etc. These articles, however, are not made to any great extent in Andalusia. For the manufacture of such cork articles as are produced there, the local factories are, as a rule, fairly well equipped with machinery, when the very low cost of manual labour is considered. The enormous waste of cork which is inevitable in the manufacture of cork articles—approximately from one-half to two-thirds of the total material—is not in reality a loss. Naturally, the best of the cork bark is utilised in cork products, and the refuse and shavings are exported to England, Germany, and the United States to be used in such valuable by-products as linoleums, cork-tiling, and other composition articles.

TRADE BETWEEN CORSICA AND THE RIVIERA.

A considerable trade has sprung up of late years between Corsica and the Riviera in agricultural and other produce, which is shipped chiefly to the port of Nice. Amongst the principal articles imported from the island are early fruit and vegetables (*primeurs*), live-stock, fresh meat, game, fish, cheese, olive oil, wine, charcoal, and timber for building.

The trade in early vegetables and fruit, which was commenced some fifteen years ago, has, thanks to the "Comité des Interêts Corses de Nice," and other similar institutions in the island, grown in importance every year. This produce is shipped chiefly at Bastia.

During the three months ending March 31st of the present year, these shipments consisted chiefly of 136 tons artichokes; Tangerine oranges, 22 tons; green peas (the earliest in the market), 20 tons; sweet chestnuts, 17 tons; onions, 45 tons; and a small quantity of apples, nuts, etc.

The trade in live-stock has been less active during the last quarter than formerly, in consequence of the high prices prevailing in the island; the numbers being 16 horses, 32 goats, and 740 pigs. The fresh meat, of which 17 tons were imported, was chiefly lamb or kid. The quantity of fresh fish—45 tons, and two tons of lobsters—was less than usual. This is due to the close season during January and February, when fishing operations were suspended.

Enormous quantities of small birds, mostly thrushes, are exported to Marseilles, Paris, and other towns in France. They are much esteemed by epicures, and are sold in Paris as "Swiss thrushes."

The cheese made in Corsica is of excellent quality. The various cheese factories established on the island during the last three years have an output of upwards of $1\frac{1}{2}$ million kilogs (1,500 tons) annually, which is supplied to the cheese makers of Roquefort, to whom it is sent to be finished and seasoned in their celebrated cellars. A special kind of cheese, made also from ewe's milk, called "Cyznosfort," is likewise a product of the island. It is said to rival the better known Roquefort. Only three tons of cheese were imported to Nice during the quarter.

The wines made in Corsica are of excellent quality, and certain growths, notably the *Cervione*, *Sartène*, *Tallone*, *Corte*, and *Cap-Corse*, are bought up by the large wine firms in Nice. The wine crop last year was an average one.

The olive crop for the last four or five years has been very good. Last year's crop in the district of Balagne, which was exceptionally good, realised upwards of six millions of francs.

The quantity of oil imported to Nice during the quarter was 365 tons; this quantity, no doubt, would have been far larger were more care taken in the process of extraction by manufacturers in Corsica. Many proprietors of oil-mills at Nice and in the department of the Alpes-Maritimes now prefer to import the raw olives, from which they extract, by more up-to-date methods, a superior quality of oil to that made in Corsica. Sixty-nine tons of raw olives were landed at Nice during the three months ending March 31st last. Charcoal is imported to Nice by the steamers of the Fraissinct Company in sacks containing 80 kilogs (176 lbs.), and in bulk by sailing craft.

The quantity of charcoal landed at Nice was 872 tons during the quarter. About 500 tons of timber for building, and 48 tons of cork, chiefly

Hosted by Google

cuttings and waste, to be used for manufacturing linoleum, etc., were also brought during the same period.

The value of the exports from Nice to Corsica is very trifling, as the principal manufactured goods are sent direct from Marseilles.

The number of passengers embarked for Corsica was 1,830 during the first three months of the present year. An expenditure of 1,350,000 francs (£54,000) for harbour improvements at Nice has just been sanctioned by the French Government, who will contribute to the extent of 675,000 francs (£27,000), whilst of the remainder, 450,000 francs (£18,000), and 225,000 francs (£9,000), will be provided by the town of Nice and the Chamber of Commerce respectively.

These improvements will consist chiefly in the construction of about 300 metres (nearly 1,000 feet) run of quays and a graving dock.

The port is frequented by vessels up to 1,000 to 1,500 tons. There is a depth of water of 7½ metres (24 feet 9 inches) in the outer, and of 6 metres (19 feet 8 inches) in the inner harbour.

ENGINEERING NOTES.

Internal-combustion Marine Engines.—The adoption of internal-combustion engines for ships marks what may be as complete a revolution in the conduct of maritime transport as, through identical means, has taken place in land road transport. A few months ago the engineering and other papers were full of the accounts of the trial trip of the "Selandia," with internal-combustion engines for her motive power. Though there are plenty of smaller vessels so equipped, especially in the case of the North Sea fishing-boats, the "Selandia" is the first ocean-going vessel of this character. Trial trips and shop experiments are, of course, valuable in their way, but the experience of an actual voyage is infinitely more so. The "Selandia" has now returned from Bangkok, after a run of 21,840 miles, with an average amount of rough weather. She called at sixteen ports, involving much manœuvring in entering and leaving them. The "Selandia" is 370 feet long, 53 feet wide, has a dead-weight capacity of 7,000 tons, and a speed of 12 knots. There are two Diesel main engines, each of 1,250 horse-power, driving twin-screws, and two auxiliary engines, each of 250 horse-power. Each main engine has eight cylinders on the Otto cycle, and runs 140 revolutions per minute. It was the longest voyage yet accomplished by a motor-ship, and everything seems to have turned out perfectly satisfactory. Further experience, no doubt, is necessary, but no inherent defects have been found in the principle of 4-cycle motor propulsion. It is proved, moreover, that 9,300 tons of cargo have been carried 21,840 miles by the consumption of nine tons of fuel per twenty-four hours, and with an engine-room crew of ten men and three boys.

There are also some other large vessels which have been launched recently to be worked on the same principle, such as Messrs. Furness, Withy & Co.'s vessel "Eavestone," built by Sir Raylton Dixon & Co., which has undergone satisfactory trials; the "Innesburg," of the Coasting Motor Shipping Co., and the "Fiona," belonging to the same owners as the "Selandia," namely, the East Asiatic Co. This company also launched some time ago the "Jutlandia," which is a sister-ship to the "Selandia," also motor-driven.

An interesting article in the *Engineer*, recently published, shows that if a vessel the size of the "Mauretania" were fitted with internal-combustion engines, and the ship built with a double skin, with an average space of one foot between the skins, making for strength and safety, the space thus provided would hold sufficient residual oil for a voyage across the Atlantic, and partly back again. The figures are given, and the article is worth attention as emanating from a trustworthy authority.

Non-ferrous Metals.—It has been rather the fashion of late in engineering circles to describe systems and things by what they are not, such, for instance, as wireless telegraphy and the trackless trolley, and now we have an important exhibition, which was held at the Agricultural Hall about a month ago, called by the name of "The Non-Ferrous Metals Exhibition." There were two hundred exhibits of a very interesting nature, such as those by the Delta Metal Company, Thermit Welding Anti-Friction Metals, Muntz Metal, and a good show by the British Aluminium Co.

The Engineering Trades.—With regard to the iron trades of Birmingham and Wolverhampton, the vexed question of a bonus for puddlers has at last been settled, and, owing to increased wages, manufactured iron prices have been advanced 3*s.* 6*d.* to 5*s.* per ton. Nearly all items in the steel and iron trade have advanced considerably owing to largely increased demand. In steel bridges, roofs, railway waggons, boilers, tanks and joists, rolled steel, steel tube strip, etc., there has been a pressure in orders which it has been difficult to meet, and in Lancashire much of the same condition of things exists, as well as in the North of England and Scotland, and in many instances orders have been received which will keep the firms busy right up to the end of the year. Vickers & Co. have launched a floating dock for Canada in three sections, and there has been a busy time in regard to ship plates. The pig-iron trade has advanced also rapidly, and 1912 promises to be a record year for several departments of engineering and the allied trades. Exceptions, however, must be made in the case of textile machinery and steam engines, the latter suffering, both in this country and in Germany, in the competition by steam turbine and central electric station work. The locomotive trade can only be said to be in an average condition.

The export of railway material of all kinds for the six months ending June last, the figures of

Hosted by Google

which have just been published, show an increase from the corresponding period of 1911 of £284,142; he total amount is £4,687,651, the principal increases being in rails, waggons and fittings, while wheels and axles, tyres and locomotives show a decrease. British South Africa and Australia are principally responsible for the increase, while as regards rails in particular, India, Australia, and New Zealand have led the way.

The electrical industries, which have been in a state of considerable depression for the last two or three years, owing, it is said, to foreign competition, have now turned the corner, and at a good many of the general meetings of the electrical supply firms which have been recently held, there has been mention of marked instances of substantial recovery, which most of the chairmen believe will be maintained. The electrical industries have such a considerable share in supplying engineering undertakings, that they are properly included in a review of this kind.

A circular has just been issued from the Midland producers notifying an advance in marked iron bars of 10*s*. a ton, making the basis £9 10*s*., with the usual 12*s*. 6*d*. extra for the Earl of Dudley's brand. The last advance was in April, due to the coal strike, and was from £8 10*s*. to £9.

OBITUARY.

David Harris, F.R.S.E.—Intimation has been received of the death of Mr. David Harris, at his residence, Lyncombe Mount, Bath, on June 17th, at the age of seventy. Born at Dunster, Somerset, he was at the age of twelve apprenticed to a provision merchant at Boston Spa, Lincolnshire. A few years later he entered the service of Messrs. Reynolds, wholesale provision merchants of London. When about twenty-four years of age, Mr. Harris was appointed as manager in Edinburgh of an insurance company. Here he made the acquaintance of the late Mr. A. B. Fleming, founder of the oil and printing-ink business, Caroline Park, Granton, N.B., and London, and, joining the firm as a partner in 1872, he continued as commercial managing director for over twenty-five years. Besides holding this post, Mr. Harris was chairman for many years of Messrs. Bertrams, Limited, the well-known paper-makers' engineers, of Edinburgh and London, and was chiefly instrumental in converting the firm of G. & W. Bertram (founded in 1821) into a limited liability company in 1888. Mr. Harris was also chairman for a long period of the great North of Scotland Granite Company, Ltd., of Peterhead. In recent years he has been chairman of some successful rubber companies of Edinburgh and London.

In addition to filling these posts, Mr. Harris was for many years a director of the Edinburgh Chamber of Commerce, a director of the Edinburgh Royal Infirmary, a Fellow of the Royal Society of Edinburgh, and a Fellow of the Statistical Society. He was also one of the founders of the Edinburgh Industrial Brigade Home for Lads, one of the directors of the Edinburgh Night Refuge—an institution where vagrants and the destitute are received and assisted—a director of the Training Home for Girls, in Edinburgh, a director of the "Mars" Training Ship for Boys, stationed in the Tay, between Broughton Ferry and Dundee; one of the founders of the Discharged Prisoners' Aid Society, Edinburgh, and of the Edinburgh Grove Laundry, which is a rescue institution for discharged women prisoners. Mr. Harris joined the Royal Society of Arts in 1884.

NOTES ON BOOKS.

War and the Private Citizen. By A. Pearce Higgins, M.A., LL.D. London: P. S. King & Son. 5*s*. net.

This volume forms No. 27 of the admirable series of monographs by writers connected with the London School of Economics and Political Science, which is being edited by the Director of the School, the Hon. W. Pember Reeves; and in the opinion of the Right Hon. Arthur Cohen, K.C., who contributes an introductory note, it is "by far the most instructive and valuable work that has been written on the Hague Conferences and the London Naval Conference of 1909." As Dr. Pearce Higgins remarks, the ordinary Englishman knows nothing of what war means from personal experience, and his object in these lectures is "in an atmosphere of academic calm . . . to draw the outline in no uncertain manner"; he wishes, in a word, to do for us legally what "The Englishman's Home" did for us in dramatic fashion.

One of the most striking sections in the book deals with the suddenness with which war may break out. The Russo-Japanese War, for instance, commenced without any formal declaration; indeed, so sudden was the action of Japan, that Russia complained to the Powers that the enemy has committed "a gross act of treachery." Dr. Pearce Higgins also quotes from a speech by Lord Granville, on taking office as Foreign Secretary on July 11th, 1870, in which he states that the Under-Secretary at the Foreign Office had informed him that never during his long experience had he known so great a lull in foreign affairs. Eight days later, on July 19th, the Franco-Prussian War broke out. The outbreak of the Turco-Italian War was even more sudden. "On September 25th 1911, the world first heard of serious complaints by Italy against Turkey. On September 28th an Italian ultimatum was presented, and next day Turkey replied in a pacific sense, and that day, at 10 p.m., Italy declared war and commenced hostilities . . . If a State is determined on war," continues Dr. Pearce Higgins, "it will seize the

Hosted by Google

moment it thinks most advantageous for making its formal declaration."

After dealing with the laws of war in relation to the private citizen, the author proceeds to discuss the questions of hospital ships and the carriage of passengers and crews of destroyed prizes; newspaper correspondents in naval warfare; the conversion of merchant ships into warships; and the opening by belligerents to neutrals of closed trade. Dr. Pearce Higgins is well known as a lecturer on public international law both in London and in Cambridge, and his criticisms of the work achieved at the Hague Conferences are as valuable as they are impartial.

GENERAL NOTES.

Social Research Prize, 1912-13.—The Governors of the London School of Economics and Political Science (University of London) offer a prize of £100 for the best essay or monograph submitted by July 31st, 1913, on one of the following subjects:—(1) An analysis, quantitative and qualitative, of the annual consumption of wealth in the United Kingdom, showing in what the total product of commodities and services actually consists, and how and by whom it is "consumed," and as far as concerns any parts of it, with what unsatisfactory or positively deleterious results. (2) The actual working and ascertained results of the Old Age Pensions Act, with suggestions for its improvement. (3) A survey of any village or small town in Great Britain accompanied by an estimate of its characteristic advantages and its limitations, with suggestions for improvements (*a*) from within; (*b*) from without. (4) A New Factory Bill, which should, without adopting any new principle, by appropriate technical clauses in Parliamentary form, extend and make applicable to every section of employed persons in the United Kingdom all the various protective provisions now applicable only to particular sections in the existing Factory, Workshops, Truck, Shop Hours, Railway and Mines Regulation, Trade Boards, Merchant Shipping, and similar Acts; with a view to securing by law to every worker such a national minimum of education, sanitation and safety, leisure and rest, and subsistence as is already prescribed by law for some workers. (5) Whether, and if so in what manner and to what extent, the best economic use of land in Great Britain, urban or rural, is prevented by (*a*) considerations of sport or pleasure; (*b*) restrictive covenants in leases or other conditions of tenancy; (*c*) life interests, trusts and other forms of limited ownership; and (*d*) the system of assessment and rating, and other methods of taxation. (6) Whether, and if so under what circumstances and to what extent, the agricultural industry as it is or as it might be carried on in Great Britain could afford higher wages to those engaged in it. If suitable monographs or essays are submitted, five, or possibly more, additional prizes will be given, value £5 each. The competition will be open to all, without restriction of age, sex, nationality, residence, educational qualifications or connection with any university or other institution. All inquiries should be addressed to the Secretary of the London School of Economics and Political Science, Clare Market, Kingsway, London.

The London School of Tropical Medicine.—At the request of the Right Hon. L. Harcourt, Secretary of State for the Colonies, a committee has been formed to raise funds for the extension and development of the London School of Tropical Medicine. In order to provide an endowment fund, to make necessary additions to the laboratories and buildings for the accommodation of the growing number of students, to provide for the active prosecution of research and to establish a small nursing home for civilians who cannot afford to procure for themselves the special medical and surgical treatment and nursing required in these very special branches of disease, the committee is appealing for the sum of £100,000. The preliminary list of contributions already amounts to upwards of £30,000. This school was founded by the Seamen's Hospital Society in 1899 under the auspices of the then Secretary of State for the Colonies, Mr. J. Chamberlain, who regarded it as the discharge of a duty owed by this country to its representatives in our tropical and semi-tropical dependencies, and as a necessary step towards the agricultural and commercial development of those territories. For the same reasons the school has received the warm support of successive Secretaries of State both for the Colonies and for India. The branch of the Seamen's Hospital at the Royal Victoria and Albert Docks was selected as the site of the school, because it is situated in the most populous shipping centre of London, and close to the wharves where vessels arrive from every part of the tropical world. On these vessels are found the victims of many of the tropical diseases, and the students who are being trained have under their observation and treatment many of the conditions and ailments with which they will have to deal in the tropics.

The U.S.A. Harvest.—The harvest in the United States this year promises to be extremely good. "If present calculations are realised," writes Dr. Henry Clews, "we shall garner a 700,000,000 bushel wheat crop, a 2,900,000,000 bushel corn crop, and a 1,200,000,000 bushel oats crop. The yield of potatoes and hay is also likely to be considerably ahead of last year. The total value of these five crops is estimated at $3,600,000,000, or about $200,000,000 ahead of last year. In all probability the aggregate of all agricultural wealth produced this year will be about $9,000,000,000, as against $8,500,000,000, the figures of the Department of Agriculture last year. What this annual production of new wealth means to this country

Hosted by Google

may be estimated when it is remembered that the capital stock of all the railroads in the United States is placed at $8,470,000,000. An increase of $500,000,000 in agricultural products in a single year cannot but be a powerful stimulus to business."

THE CENSUS RETURNS.—The second volume of the detailed abstracts of the Census returns, just published as a Blue Book (Cd. 6259), contains the population figures of registration counties, districts, and sub-districts, and also the aggregate number of marriages, births, and deaths registered in each registration county and district during the years 1901–11. The number of families (denoted by the number of schedules returned) is found to be 7,970,660, and the number of members 34,776,402, an average of 4·4 for each family. In all counties the births registered outnumbered the deaths, so that had there been no migration the population in every county would have been greater in 1911 than in 1901. But, as a matter of fact, of the fifty-five registration counties there were seven—London, Cumberland, Westmoreland, Cardigan, Radnor, Montgomery, and Merioneth—in which the population decreased. These seven counties had not only lost all their natural increment, but something over and above, owing to losses by migration. There were thirty-one other registration counties in which the actual increase was less than the natural increase, while in the remaining seventeen counties the actual growth, as shown by enumeration, was in excess of the natural growth, as shown by excess of births over deaths. Of the seventeen counties which absorbed population from without, some of the largest gains from migration were in the counties surrounding London—namely, Middlesex (22·7 per cent.), Surrey (15·5 per cent.), Hertford (8·9 per cent.), and Essex (8·5 per cent.); while two counties, in which mining is the leading industry, also showed considerable gains—namely, Monmouth (10·9 per cent.) and Glamorgan (10·6 per cent.). The aggregate number of marriages, births, and deaths were respectively 2,641,170, 9,290,058, and 5,245,411, showing an increase of population of 3,542,649, and an excess of births over deaths of 4,044,647.

INTERNATIONAL EXHIBITION OF ARCHITECTURE AT LEIPZIG, 1913.—An international exhibition of architecture and building construction will be held next year at Leipzig under the patronage of the King of Saxony. Special facilities will be granted to foreign exhibitors by the custom house authorities and on the railways in Saxony.

PRODUCTION OF RICE IN JAVA, 1910.—The production of rice in the island of Java, according to an Italian Consular report from Batavia, amounted in 1910 to 82,866,916 pikuls,* or 4,932,554 English tons.

* The pikul equals about 133⅓ English lbs.

THE BRICK AND TILE-MAKING INDUSTRY IN DENMARK.—Brick-making in a country like Denmark, destitute of stone, where the buildings are chiefly constructed of brick, of necessity must be an important industry. There are upwards of 200 works throughout the kingdom where bricks and tiles of every description are made. Denmark, notwithstanding, imports a considerable quantity of these materials annually from her neighbours, chiefly the south of Sweden and from some of the outlying islands. The cost of carriage by small sailing craft is very low. There is no import duty on bricks and similar materials in Denmark. A considerable quantity of bricks and tiles, both ordinary and glazed, are also imported from Germany. Fire-bricks and fire-proof tiles for lining stoves, furnaces, etc., are brought from these countries as well as from England. It is possible that the brick-makers of Kent might find a good market for their products in Denmark, especially for the superior qualities of bricks and tiles.

MANUFACTURE OF ORIENTAL CARPETS AT MISRATA.—Misrata, just occupied by the Italian troops, is one of the most important, if not the only manufacturing town in the provinces of Tripoli and Cyrenaica. Situated near the coast, about 120 miles east of the town of Tripoli, Misrata, besides various other industries, has been famous from time immemorial for the weaving of the richly coloured Oriental carpets and rugs known throughout the East by its name. The characteristic designs and hues of these carpets are now successfully copied by the Germans, who have for many years past inundated the bazaars of most of the towns on the North African coast with their clever imitations, which are difficult to distinguish from the genuine article. The town, which is situated in a fertile oasis surrounded by trees and gardens, is inhabited by many wealthy residents chiefly engaged in trade and manufacturing industries; and they no doubt will soon learn to appreciate the new *régime*.

THE TRADE OF COSTA RICA.—The Italian Consul at San José, in his report on the trade of the Republic of Costa Rica, states that the total value of the exports from that country in 1911 amounted in value to 18,009,385 colones (£1,721,740), and the imports during the same period to 16,044,444 colones (£1,533,876). The chief articles of export, which are principally to the United States and England, were bananas, coffee, cacao, hides, sugar, sugar-cane, mahogany, mother-of-pearl, gold and silver in bars. The imports, which are chiefly from the United States and Europe, were dry goods, hardware, provisions, railway material, and general merchandise. The imports to Italy at the present time are comparatively insignificant—on the other hand the exports from that country to Costa Rica have a certain importance; the principal articles were felt hats, umbrellas and parasols, marble, wine, vermouth, and a variety of other goods.

FRIDAY, AUGUST 23, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C

NOTICE.

CANTOR LECTURES ON "THE MEAT INDUSTRY."

The Cantor Lectures on "The Meat Industry," by Mr. Loudon M. Douglas, F.R.S.E., have been reprinted from the *Journal*, and the pamphlets (price one shilling) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, London, W.C.

A full list of the Cantor Lectures which have been published separately, and are still on sale, can also be obtained on application to the Secretary.

THE RAJPUTS IN THE HISTORY OF HINDUSTAN.

By Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D.

Part I.

"His hidden meaning dwells in our endeavours,
Our valours are our best gods."
John Fletcher, *Bonduca*.

We stand at the present moment at the parting of the way followed by us for the past 150 years in India; and if we would take true divination of the goal, on the right hand or the left, whereto our searching arrows are winged, nothing could be more helpful to us than a close study of the character and the history of those who before us have held paramount power over the country,—the warrior caste of Rajputs, the priestly caste of Brahmans, and the fierce Islamites [Arabs, Afghans, and Mo(n)gols] who held both in more or less complete subjugation throughout the 1,046 weird, penitentiary years preceding the revindication of Aryan supremacy in India under the mighty seven-fold shield of the "British Raj." This paper treats only of the Rajputs; and on the basis of Miss Gabrielle Festing's "From the Land of the Princes," and Colonel James Tod's "Annals of Rajasthan." Miss Festing's book does for the stirring national traditions, and dynastic chronicles of Rajasthan, "the land of Kings," what Charles Kingsley and the Rev. Alfred J. Church did for the tales, from Homer, Hesiod, and Herodotus, of the gods and heroes of ancient Greece. She has epitomised the bardic legends, or *rashas*, as they are termed by the Rajputs, or "Sons of Kings," which were first systematically gathered together for English readers by James Tod; who, going out to Calcutta at the impressionable age of seventeen, after serving in the Intelligence Department of the Army during the operations undertaken by Lord Hastings in 1817 against the Pindaris, was appointed in 1818 Political Resident at Udaipur, the capital, in succession to Chitor, "the Painted," of Mewar, "the Mid-ward" * of Rajasthan.

The Four Castes of Hindus.

The Hindus hold the *Maharana*, or "Great-King" of Udaipur, as the reputed descendant, in the direct line of primogeniture, of the eponymous hero of the *Ramayana*, and, of divine right, the absolute head of the Solar Rajputs, to be sacrosanct above all other Rajputs; these Solar Rajputs, with the Lunar Rajputs, or descendants of the kin Kaurava and Pandava Princes, the antagonistic heroes of the *Mahabharata*, constituting the *Kshatriya* [*cf.* "Satrap"] or "Sovereign" caste, the second,

* The Hindus designate the whole country between the valley of the Indus and the valley of the Jamna and Ganges, and between the Himalaya and the Vindhya mountains, *Madhya-desa*, *i.e.*, "the Middle Land"; the Mahrattas apply the term to the country between the Konkans and Khandesh; while all Hindus refer to the cradle of their race in Central Asia as *Madhya-bhumi*, *i.e.*, "the Middle-Earth." The Sikhs similarly name the land round about Lahor, as the original home of their sect, *Manja*, a local form of the Sanskrit *madhya;* this word, over all India, also meaning the land between any two villages, "the Hub of the Universe" for each village. "Media" is probably the same word.

Hosted by Google

after the *Brahman* or "Priestly" caste, of the three "Twice-born" sections [the third being the *Vaishya* or "Settled" caste of traders], into which the primitive Aryan invaders of India, under the operation of the natural and economic influences, systematised by the "Code of Manu," and similar law books of the Hindus, became separated; the fourth Brahmanical caste of *Sudras*, or "Shattered-serfs," representing the subjugated aborigines,* or, at least, the pre-Aryan people of the country.

RAJPUTANA.

Seventy miles westward from Udaipur, at the angle formed by the northward emergence of the Aravali Hills from the Vindhya [" Dividing" between Hindustan and the Dakkan] Mountains, towers, to the height of 5,650 feet above the sea, the abrupt dome of Mount Abu [Arbuda], famous for its Jaina temples—like the wonderful Jaina temples, rising terrace upon terrace, up the slopes of the Satrunjaya Hill in Kathiawar—all of white marble, sculptured outside and inside, both pillars and roofs, with the finish and refinement of carved ivory or ebony, an ecstasy of the art of mystical architecture: "a Satanic mockery"—as the revered Dr. John Wilson, with pardonable professional prejudice, once pronounced them—"of that heavenly Jerusalem whereinto shall nowise enter any thing that defileth." This cone, the *guru-sikhar*, "Saint's Sanctuary" [literally "Pinacle"] of the Jainas, is the culminating point of the Aravalis [literally "Row of Peaks," "Stockade"]; the "strong Refuge" of the Rajputs when overwhelmed in the flood of the successive Mahometan invasions of India from the eighth to the eighteenth centuries A.D.; and again when, driven by outrageous oppressions, senselessly prosecuted through successive centuries, they from time to time revolted against the Afghans and the Great Mo(n)gols. From Mount Abu the Aravali Hills range boldly north-eastward, straight as an arrow, through the midst of Rajputana, "the Land of Princes" [called also Rajwara,* "the Ward—the Dwelling-Place of Princes"] for about 200 miles; whereafter they begin to decline from their pre-eminence, and become more and more disconnected; cropping up again before they finally disappear under the alluvium of the plain of the Jamna, in the historic "Ridge" at Delhi, 360 miles north-east of Udaipur. As now restricted to the States lying between the Indus and the Jamna, a little less than one-half of Rajasthan—that is Marwar [Jodhpur], Jeisalmir, Bikanir, and Sirohi—lies to the westward of the Aravalis, and is watered only in Marwar and Sirohi, by the "Salt" Luni, as it flows southward to the Rann, or salt-"Waste" of Cutch; and a little less than one half—that is Mewar [Udaipur], Amber [Jaipur], Kotah with Bundi [Haraoti], etc., watered by the many affluents of the Chambal, as it flows north-eastward to the Jamna—lies to the eastward of these hills. The British province of Ajmir, "Aja's Hill," with Mairwara, "the Highland-ward" [compare Mount Meru], extends over the middle third of their crest; the City of Ajmir, dominated by Taragar [" Star-garth"] 2,855 feet above the level of the sea, making the point wherefrom the Aravali Hills begin to decline toward Delhi.

Situated on the verge of the Tropic of Cancer, Rajputana falls within the Northern Solstitial Zone; the desert tracts of Persia, Syria, Arabia, the Sahara of Northern Africa, and the *Tierra caliente* of Mexico, marking other, so to say, broken links of the Earth's close clinging girdle ["shingles"] of fire and famine. Where not an absolute desert, as in the Thul, *i.e.*, "The Deadly-region," between the Luni and the Indus, and parts of Marwar, *i.e.*, the "Deathward," or "Grave-yard," Rajputana is still an arid, and, for the most part, sterile land; but relieved within the morning and afternoon shadows of the Aravalis,—intermittently along the banks of the brackish Luni, and continuously, and in greater breadth, in the courses of the Chambal and its contributories,—by green tracts of wild woodlands and herbage, and of cultivated fields and orchards, and pleasing gardens; and further diversified by the mediæval walled towns, uprising on the rock-crested ridges

* The word used in the *Mahabharata* and the *Rig-Veda* for the people the Vedic Aryas found in India is *daysu*, the equivalent of the Hindustani *deshi*, *i.e.*, "of the country"; but the Vedic and Epic term *daysu* includes brown Hamites [Dravidas], and yellow Turanians [aboriginal Bangalas], as well as absolute autochthons, probably, of the Negroid [blackish] colour of the Andamanese. The Sanskrit word for "caste" is *varna*, literally "colour"; and caste, in its origin, was the colour-line between white and brown, and white and yellow, and white and black, men in India; and between shades of these mixed colours, the Sanskrit word for the innumerable Brahmanical sub-castes of the present day being *varna-sankhara*, and meaning, simply, "colour-intermixture," "colour-confusion." In the phrasing of ethnologists, India west of the confluence of the Ganges and Jamna, and southward into Gujarat and Kathiawar is "India Alba"; east of this confluence and on into Burma, "India Flava"; and Southern India, the Carnatic, "India Nigra."

* The familiar Rajput denomination of Rajputana is Rajvara; *vara* here, not being used in the sense of "ward" exactly, nor of "heaven" [*cf.* "pan-orama"] or "property" [*cf.* Trolsworthy in Devonshire], but rather of "warren," with the meaning of "our own endeared home-land."

Hosted by Google

of sand rippled over the wide extended plains, as if so many islands, or so many huge turreted ironclads riding grimly at anchor, moored with two anchors, on a swelling sea. Vast herds of camels and horned cattle, and innumerable flocks of sheep, ever in search of new pastures, freely wander everywhere; and behind all is the more or less distant background of the everlasting Aravali Hills with their shimmering peaks of white and rose-coloured quartz. The varied prospect, with its contrasts so harshly accented by the dry glitter of a sub-tropical midday, as seen embalmed and harmonised in the softer amber light of morning, or suffused with the refreshing rosy flush of evening, is at once transfigured to a fairy land. In a moment, one's own soul is brought face to face with, as it were, the very soul of the soil, and its foster-children, and their history, and their autochthonous gods, —the gods of the land; and the impression thus suddenly created by the transient scene, abides for ever with the spell-bound beholder.

James Tod.

At Udaipur young James Tod was fascinated by everything around and about him; by the spiritualising picturesqueness of the landscapes; the gay colourings of the Palatine Cities—the white and green of their painted houses; the rose madders, and other reds, and lemon and saffron yellows, and cobalt and indigo blues of the nodding turbans, and swaying girdles, and twinkling shoes, of the white-robed people in the spacious streets; and the vermilion, and Chinese yellow, and indigo-blue flags of all the gods, fluttering among the green trees in every air of heaven that breathes about the frequent temple spires; and by the lofty Palaces of the Rajput Princes, and the stately splendour of their military Courts, and their own manly, gallant bearing and fine "civility of manners, arts, arms, and long renown." Beyond all else he was moved by their old feudal fortresses, and the shrines and temples of their gods, instinctively adapted as these are to the sentiment of the country and its inhabitants, and their chivalresque history. Seen day by day in sunshine and shadow, and month after month in all the glamour of the full moons of India, and sketched and painted over and over again by himself, it was the aerial architecture of the visionary summits and peaks of the Aravali Hills that, to the subjective sensibility of James Tod, touched Rajputana with supreme enchantment. With an industry, assiduity, and perseverance, only enthusiasm like his, and fed like his on "the corn of heaven," could so strenuously have sustained, he devoted whatever leisure he obtained from his official duties during the years 1818–22, to the study of the physical geography, ethnography, and history of Rajputana; and of the social, political, and religious system under which it had been governed by its famous princes; and to the collection of their genealogies and family legends, and traditions, as these are found epitomised and embodied in his "Annals and Antiquities of Rajasthan." This work is an inexhaustible storehouse of the known and accessible information of the Rajputs and of Rajasthan, as limited by the modern official Circle of Rajputana; and although in the present day its author's conclusions on certain moot points of obscure ethnology, and obscurer etymology, may be questioned, it remains the standard history, and will always remain the classical history, of Rajasthan. It is simply amazing how its author could have amassed the materials for its production, and reduced them from chaos to the fair and lucid order in which they are found in his pages, and within the years, which were also otherwise well-laboured years, of his all too brief life; for he died, as Colonel Tod, in 1835, at the age of fifty-three. But the work, contained in two bulky volumes, in imperial 8vo, has long been out of print, and is rarely to be found even in the catalogues of the sales of second-hand books. Moreover, it is too solid and preoccupying reading for the present day of superficial knowledge and professional culture. It is "*caviare* to the general," and outside the British Museum and our University Libraries it is now to be found only in the houses of families that have inherited copies from relatives connected with the Honourable East India Company; standing beside the treasured "Oriental Memoirs" of James Forbes, the grandfather of Montalembert, the "History of the Mahrattas" of James Grant Duff, the father of Sir Mountstuart Elphinstone Grant-Duff, and the "Ras Mala" of Alexander Kinloch Forbes: three books that everyone responsibly associated with the Indian Empire should read, and ever keep beside him, or for ever hold his tongue off India.

Miss Festing's "From the Land of the Princes" would, therefore, have been more than justified if only for its attracting wider attention to a work of such rare originality and authority as Tod's "Annals and Antiquities of Rajasthan," a veritable "Open Sesame" to the heart and mind and soul of the great, and sacro-

Hosted by Google

sanct military caste of India; and the only Hindu caste with any inspiring and controlling traditions of political power and responsibility. But her handy volume has its own independent value, in the very qualification of affording a clear insight into the character and ideals of the Rajput Princes, which renders Tod's two unwieldy volumes invaluable for those who would acquire a true understanding of the people of India. Her collection of stories is all of definite, and unimpeachable family traditions and documents, selected with careful discrimination, and in the diligently observed order of their proper chronology and topography; and in the things that are profitable for inspiration and example, and therefore alone essential to historical teaching, they are faithful transcripts in prose of the *rashas*, or "bardic annals" of Mewar, Marwar, Amber (Jaipur), Haraoti [Bundi and Kotah], and Jeisalmir. Miss Festing's book, therefore, cannot but exert a salutary influence in promoting in this country a more intimate knowledge, and a more intelligent understanding of India, and arousing among us a feeling of generous and romantic sympathy with the noble *Kshatriya* caste of Rajputs; and of radical brotherhood with the "twice born" castes of Hindus generally, Brahman, and Rajput, and *Vaishya;* who in blood, and brawn, and bone, and in their ineradicable virility, are one and the same Aryan people with ourselves. The very word that labels our ethnical unity with them is taken out of their own mouths, and in its original sense; and amongst the earliest derivatives from it are the Sanskrit and Old Persian words signifying "brave" [*cf.* the Greek War-God Ares], and "truthful," and "noble" [*cf.* Greek ἄριστος] and "friendly."

THE ARYAS IN INDIA.

The Aryas of the prime, as they descended on India from the "officina gentium," some vague where about the Euxine, Caspian and Aral Seas, the "seething pot, and the face thereof toward the North" of the perfervid vision of the prophet Jeremiah, may have been mixed of all the ethnical stocks, Caucasian or Noachian, and Scythian* of Central Asia; but without doubt they were predominantly of the Aryan or Japhetic stock, speaking the language from which Sanskrit and Zend [Old Persian], Greek and Gothic [Teutonic], Latin and Romance have all been derived. As they pushed farther Eastward across Hindustan, and later Southward, down into the Dakkan, "they set up everyone his throne by the way," subjugating to themselves the Caucasian Hamites [represented by the Dravidas of Southern India] and Turanian ["Yellow" Scyths] and Nigritian [Negroid] peoples already in the peninsula. And as their paramount position was thus consolidated in the country, two things happened. They were no longer an army on the march. They had formed larger and smaller settlements, needing only a central garrison for their defence. Multitudes of the warriors thus fell out of occupation, and these, turning their energies to trading, in the process of the centuries became the *Vaishya* caste of Brahmanical India. It was a straightforward, frank solution, of a pressing economic problem. But the development of the reproductive resources of a country, and of mercantile relations with contiguous countries, has ever had a humanising influence on man; and the initiation of this process of national and social evolution by the unemployed Aryan warriors in India, proved the beginning, as in a grain of mustard seed, of the implacable and destructive conflicts that were to rage for centuries in a far-off future between the commercial and internationalised Buddhists, and the priestly and emmordantly nationalised Brahmans, when as yet there were none of either of them. At first every Arya was a king and priest unto himself, his family, and his state. But now and again a poet of genius had appeared among them, chanting his own improvisations to cheer his comrades on their ceaseless marchings and counter-marchings, or to rouse their courage on "the Field of Slaughter" to its highest fire. The "Hymns" of the *Rig-Veda*, the only true *Veda*, are the lyrical heart-burst of the devout joy of the Aryas [a transport of religious emotion that thrills the world to the present day], when, after their weary wanderings among the inhospitable uplands of Persia and Afghanistan, they at last stepped down into the immense extended, well-watered, and semi-tropical plains of the Panjab. A special reverence was rendered to such gifted men, and was continued to their children, and children's children, as the keepers, locked up within their trained and specialised memories, of these psalms and hymns and spiritual songs; now regarded as, in themselves, the ever-living Word of God, and

* The Scyths of classical writers were not unmixed Turanians, or "Yellow-men." The "Royal Scyths" of Herodotus have many Aryan characteristics; and the Turks and Indian Mo(n)gols can hardly be distinguished in their physical, emotional, and intellectual features from pure Aryas. The true "Yellow," and the true Black races, are outside the Caucasian [Aryan, Hamitic and Semitic] or Noachian Pale, and the genealogies of Noah.

Hosted by Google

as arming their custodians with the prerogatives of actual divinity. The remaining fighting Aryas becoming more and more preoccupied with their administrative and military duties, whether as sovereign rulers or feudal vassals, the hereditary guardians of the Vedas, or sacred *rashas*, gradually monopolised the service of the priestly duties theretofore incumbent on every Arya to discharge personally, and thus became gradually segregated as the caste of Brahmans from the similarly differentiated castes of *Kshatriyas* and *Vaishyas*. The usurping Brahmans, in their sacerdotal intolerance of the natural superiority of the Rajputs, sought to brand them with an artificial inferiority, not only by writing them down second in the order of their four theocratic castes, but by striving, and on the whole with remarkable success, to impose upon them all manner of ceremonial disabilities. This is already indicated in the *Aitariya Brahmanam*, an Appendix to the *Rig-Veda*, giving for the guidance of the Brahmans the earliest glosses on the Sacrificial Prayers of the *Veda*, with speculations on their origin and explanations of their ritual. The English translation of this *Brahmana* by Martin Haug was published by the Government of Bombay in 1863, and in Book VII., chapters iii. iv. and v., and Book VIII., chapters ii. iii. iv. and v., we have a clear insight of the means used by the Brahmans, as increase of appetite grew by what it fed on, to magnify their sacred office, and exalt themselves over the Rajputs, not only in the sphere of their spiritual life, but in the very domain of their inherent and indefeasible temporal authority and power. The story of Parasu Rama, "Rama of the Axe," who "cleared the Earth twenty-eight times" of the *Kshatriyas*, and gave it—India—to the Brahmans, is another myth of the immemorial rivalry between the Brahmanical hierarchy and the *Kshatriya*, or Rajput regal straticracy.

The Fire-born Rajputs.

The irresoluble hostility of the Brahmans toward the *Kshatriyas* is shown also by the much later myth of the origin of the Agnikulas or "Fire (born) family" of Rajputs. They are said to have been raised by the royal and saintly Agasthya, the reputed author of so many of the "Hymns" of the *Rig-Veda*, from a sacramental fire kindled on the summit of Mount Abu [Arbuda], in the presence of a convocation of the whole college of Brahmanical gods. These Agnikulas are:—(1) the Paramaras, Pramaras, and Powars or Puars, *i.e.*, "Premiers," of whom Chandragupta, the Sandracottus of the Greeks, and the illusive Vikramaditya, the great champion of the Brahmans, are both claimed as members; (2) the Pariharas, formerly of Marwar and Idar, but now found only in Central India, and the Dakkan; (3) the Chalukyas or Salunkis of ancient Ayodhya [Oudh], and mediæval Saurashtra [Kathiawar and Gujarat, called also Valabhi or Balabhi], who are still represented by the Bhagela Rajputs of Rewa, the Jhala Princes of Drandgra, Limri, or Limdi, and Wadwan in Kathiawar; and (4) the Chauhans of Rajputana and Malwa, of whom Prithvi-Raj of Delhi, Ajmir, and Lahor, the Paladin of the Rajputs in their earliest conflicts with the Mahometan invaders of India is the most illustrious name, and who are at this day represented among the rulers in Rajputana by the Deoras of Sirohi, and the Haras of Haraoti [Kotah and Bundi]. The legend probably refers to the enlistment in the third and second century B.C. of Zoroastrian Persians, and Pagan Greeks into the *Kshatriya* caste, as supporters of the Brahmans against the older recalcitrant *Kshatriyas;* or it may be simply an allegory of the hallowing of the warrior caste by the fire of their lives of devoted self-sacrifice. According to the traditions of the Rajputs, who claim to be descended from the *Kshatriyas* of the primitive Aryas of India, these are still represented in Rajputana, in the Solar-line, by (1) the Grahilot, Gehelot or Sesodia Princes of Mewar [Udaipur], Dungarpar, Bansvara, and Shapura,—and the Gohil Princes of Bhavnagar and Palitana in Kathiawar are of the same clan; (2) the Kuchwaha Princes of Amber [Jaipur]; and (3) the Rathors [originally from Kanauj] of Marwar [Jodhpur], Kishengahr and Bikanir; and in the Lunar-line, by (1) the Bhati Princes [descended, in the pedigrees of Yadavas or Jadons, from *Krishna*, the "deus ex machina" of the *Mahabharata*] of Jeisalmir; and (2) the Jadija or Jharija Princes of Cutch, Gondal, and Morvi, in Kathiawar. Nevertheless, the Brahmans persist with the calumny that none of the primitive *Kshatriyas* survived the massacres of "Rama with the Axe," and that the Agnikulas, of their own creation, are the only Rajputs now existing in India. The contention is absurd. The Rajputs, who never lost their pride of Aryan race, never hesitated to recruit their ranks by the admission of desirable aliens from over "the North-West Frontier," whether Greeks, or Sassanian Persians. A Greek prince is traced in the genealogical list of the Rathors of Kanauj and Mewar; and, in the

Hosted by Google

fifth century A.D., one of his successors married the daughter of Barham Gaur [Varanes V.]; and there is a tradition among the Gehelots of Mewar of an ancestress in the sixth century A.D. who was the granddaughter of one of the Christian Cæsars of Byzantium. My own opinion, based on personal knowledge of the men themselves, is that the purest Aryas of India are to be found among the Jainas, descendants of the Aryas who became *Vaishyas*, and then, influenced by the tenets of Buddhism, formed themselves into the heterodox sect of Vaishnava Hindus, named after "the twenty-four Victorious Jins" [*cf.* Arabic *jinn*, and "genii"], or deified saints, the objects of their especial worship. They form the prosperous and highly influential community of merchants and bankers known everywhere in Rajputana, Malwa, and Gujarat, by the style and title of *Mahajans;* and, soiled with all ignoble use by the money-lenders who have made the name of *Marvari* a byword throughout India, the appellation means, and still upholds, the ideals of a "great gentry."

The National Præcognita of Rajput History.

Apart from coins, and inscriptions on temple walls and other enduring structures, and a vast number of "copper plates" commemorating grants to temples, and the registers, ledgers, and similar documents accumulated in the current business of administration, constituting the *chalta daftar* [literally "walking parchments," *cf.* διφθέρα of Greeks] used by Grant Duff when writing the "History of the Mahrattas," the Hindus possess few authentic records, provided by themselves, of their own history; and, in attempting to reconstruct it, we have to depend on the arbitrary references to past events to be found, generally mythologised out of all recognition of their real form, in the *Vedas*, *Puranas* ["Olds"] and other sacred scriptures; and in such secular romances as the *Prithviraj Chauhan Rasha* of Chand Bardai, the Poet Laureate of the last Hindu King of Dehli; the *Raja Tarangini*, with its continuations [the *Rajavali* and others], of the Rajas of Cashmere, in the Kaurava line of the Lunar *Kshatriyas;* and the *Raja Tarangini* of Amber [Jaipur], giving a similar list of the Kings of Indraprashta or Delhi, from Yudisthira, the eldest of "the Five Pandavas of the *Mahabharata*," to Vikramaditya of Ujain and Delhi, composed so late as the early part of the eighteenth century, for Savai Jai Sing, the builder, all in white marble, of the gracious city of Jaipur. Mere facts, even the obvious convenience of cardinal dates, are quite beyond the scope of history as understood by Hindus, to whom its teachings, as apprehended and applied by themselves, would seem to have been all they ever cared to heed; and wrested from the truth, and allegorised for doctrinal purposes as the actual events dealt with by them may be, this having been done with the sincerity of religious zeal, they have intuitively expressed their grateful sense of the dealings of Divine Providence with them, as a favoured people, in devotional, and epic, and ballad poetry, singing and making melody in their hearts to the great gods to whom they raise their soul-moving and animating strains of exaltation and blessing and glory in the highest. The composite "Sesostris" [Seti I. and Ramses I., II., III.] of the Greeks may have sent a naval expedition against Western India; Darius Hystaspes certainly stretched out his sceptre over North-Western India, or Sindh and the Panjab; but there is no definite date in Indian history, before that transmitted to us by the Greeks, of the crossing of the Indus near Attock ["the Limit"], in the midsummer of 329 B.C., by Alexander the Great; while the continuous history of India, the earlier chapters of which we owe to the Mahometan writers of Arabia and Persia, only begins with the momentous apparition of the conquering armies of Islam in Sindh, A.D. 711; at the very time [A.D. 713] that another Muslim army, under its one-eyed leader Tarik ibn Zayad, was striding the Straits of Gibraltar, "the Hill of Tarik" into Spain.

The thousand years [1,037 years] between the advent of the Greeks and that of the Mahometans in India is a period of intolerable confusion for the systematic historian. But, viewed in the light of the following millennium [1,111 years] of "the Mahometan Terror" in India, the conclusion is justifiable that the previous period was also ennobled by the like dauntless and indomitable resistance of the *Kshatriyas* to the Scyths—whether of the Turkman or the Mo(n)gol races, who then commenced to pour ceaselessly into India—as in after centuries they opposed to their Mahometan conquerors. The shadows of the mighty names of the period are, (1) Chandragupta [316–292 B.C.],—variously regarded as a Lunar *Kshatriya*, an Agnikula, and a *Vrishala*, or *Kshatriya* degraded to the status of a *Sudra*, for neglecting the service of the sacred rites,

Hosted by Google

and to consult the Brahmans,—the "Sandracottus" who drove the Greeks out of the Panjab and Sindh, and married the daughter of Seleucus I.; (2) his grandson Asoka [260–220 B.C.], the wilier Constantine of Buddhism; (3) Kaniska, with the assigned date of 40 B.C., another patron of Buddhism, whose reign marks the culmination of the political ascendancy of the Scyths,—Dhes [Dahæ], Jats [Getæ, Goths], Hunas [Huns], and others—in India; (4) Vikramaditya, *i.e.*, "The Blazing Sun" of Righteousness, the Melchizedek of the Hindus, surnamed Sakhari, "the (slayer) of the Scyths" [Sakas or Takas]; and (5) Salivahana, a Mahratta potter of Paithan in Maharashtra, also surnamed Sakhari, from whom the Rajputs of Bezwara are descended. Both Vikramaditya and Salivahana are held to have been contemporaries with Kaniska, and are both revered by the Brahmans as persecutors of the Buddhists, and the unresting, strenuous, and ever victorious assailants of the Scyths. Yet "the Saka Era," so named in honour of Salivahana, "the Slayer of the Scyths," commences A.D. 78, and the "Samvat Era," established in honour of Vikramaditya, commences in 57 B.C.; while the bloody battle of Korur, in which the Scyths were finally brought down by Vikramaditya from their paramount political position in India, is dated by the expert chronologists of Europe between A.D. 524 and 554. Of such are the bewildering entanglements, obstructing the symmetrical treatment of Indian history between the exit of the Greeks from the darkened stage, and the entrance upon it of the Mahometans. The Brahmans utterly ignore the invasion of Alexander the Great, and we only know that they did at the time recognise the presence of the Greeks in their midst from their including in their list of *Vrishalas*, a people they call the *Yavanas* [compare "Javan"], by whom they undoubtedly indicate the Greeks [*i.e.*, "Ionians"], although this designation is found to include the Scyths, and even the Mahometans of Hindustan: in short, any *mlecha*, or white-faced "barbarian" from the North or West of India. In the form of *Jonakan* it is still applied in Southern India to the Mopplas of Malabar.*

THE ISLAMITES IN INDIA.

I. THE ARABS.

Within four years of the death of "the Prophet of God," A.D. 632, the Caliph Omar built Bassora, in order to control the course of the lucrative trade of India, Persia, and Arabia with Europe; and in A.D. 647 the Caliph Othman sent ships from Bassora to reconnoitre the coasts of Western India between Broach, representing ancient Barygaza, the port of Saurashtra, and Tanna, in mediæval times representing ancient Kalayana, and itself represented in our modern days by Bombay, the great emporium of Maharashta, and the commercial and intellectual, although not the titular, capital of British India. But the Arabs, a Caucasian or Noachian race, and highly intellectual people, who had with the keenest alacrity and zest entered into the inheritance of all the wisdom of the Greeks, alike in the arts of war and peace, at once perceiving that before the opulent prize of India could be appropriated with any hope of its undisturbed retention, Afghanistan, the Barbican, or "Antemural" to the "Bayley-yard" of Hindustan, had to be permanently occupied, the Caliph Muaiwah I., A.D. 664, equipped an enormous army for the conquest of that country; a prescient and sagacious task, to the accomplishment of which fifty years of arduous and steadfast fighting were doggedly devoted; although in vain, for any perenduring advantage it was to bring to the Arabs. A detachment from the force was at the same time sent, in charge of Mohalib, to make a reconnaissance of the approaches into Sindh; and when the military and religious reduction of the Afghans was sufficiently assured, the Caliph Walid I., after a survey of coasts of Baluchistan, Mekran, and Sindh, in A.D. 705, in A.D. 711 fitted out a naval expedition, under the command of Muhammad ibn Kasim, acting in co-operation with Hijaj, the Governor of Bassora, for the subjugation of Sindh. Muhammad Kasim sailed boldly up the Indus to Bakkar [some say he landed at Deval, "the Temple," near the modern Karachi], and thence marched on Alor, and after a brief campaign annexed the whole of Sindh, from the delta of the Indus to Multan, to the Ommiad Empire of Damascus. Dahir, the Rajput Deshpati, that is, "Despot" [*desh*, "land"; *pati*, "lord"], of the country made a most determined defence; but in every implement of war he was hopelessly "outclassed" by the newly-gotten "Greek science" of the Arabs. There is presented to the eye all the picturesque pageantry of Agincourt, as illuminated on the pages of Michael Drayton, the brave show in the brilliant sun of lines upon lines of glittering steel, and of flapping

* I have been greatly assisted in working out this paragraph by Mrs. W. R. Rickmer's "Chronology of India," a work that calls for the most grateful acknowledgments of all students of Indian history; and worthy of a daughter of the great Free Kirk Missionary to India, Alexander Duff.

Hosted by Google

banners, and fluttering banderolles, of every "tincture," each with its own "armings,"—not one

"But something had pight that something should express,"—

and of gorgeous trappings and caparisons of horses and horsemen, and camelry, and towered elephantry, all in solid array; and, as "the drums begin to yell," the sudden tumult and shoutings in the ranks, and the rush and clatter of hoofs, and the flash and crash of arms at close quarters, with the confused battle swaying backward and forward, as

"The Trumpets sound the Charge and the Retreat,
The bellowing Drum the March again doth beat."

But it is not war; and with the setting of the sun all that gay and gallant chivalry of Sindh of the *Kshatriyas* is seen rolled in blood and dust; and the tragedy of Alor closed with burning and fuel of fire in the terrible and woeful Rajput rite of the *johur* [Hindi *júhar*, from Sanskrit *yódhri*, "warrior"]. Dahir fell fighting in the thick of the Arab cavalry; but his widow continued the defence of the city until the exhaustion of provisions for the garrison. Then she, and all the women, with their children, gathered themselves together, and built up a great funeral pyre in the garden of the Palace, and, mounting it, were sacrificed in the flames of their own kindling; and the men having bathed and duly gone through the other ceremonies of the sublime "office," sallied forth, sword in hand against the enemy, and perished to a man. This is the immemorial Rajput ritual of the *johur*.

After Sindh, Muhammad Kasim annexed Gujarat; and thence marched on to Mewar. When, according to the vague traditions of the Hindus, Valabhi, now Vala, in Kathiawar, was stormed by a Persian king—Naushirvan the Great, 530–78, is the king named—the widow of the slain Rajput king, fleeing into the desert of Western Rajputana, there prematurely became the mother of a son [and heir to his father], known as Prince Goha. He established himself at Idar, and is said to have married a daughter of Naushirvan, by a wife who is said to have been a daughter of one of the Emperors of Constantinople—Maurice, 582–602, being the Emperor named. The seventh from the posthumous Prince Goha was Prince Bappa, who, on hearing that the Arabs had entered Mewar, collected a following, and inflicted a crushing defeat on them, and raised himself to the *gadhi* [literally, "a cushion," which, placed on a carpet, is a Rajput Prince's sovereign seat]: and it is from him that the reigning Ranas of Udaipur are lineally descended. The Arabs in India never recovered from this reverse; received at the very moment of their overthrow, at the other extremity of their far-stretched empire, by Charles Martel, on the glorious green fields between Poictiers and Tours, A.D. 752. The Rajputs in Sindh rose successfully against them in 750; and on their attempting to re-enter India from Kabul, under the command of the Mahometan Governor of Afghanistan, a relative of the Abassid Caliph, Harun al Rashid, the Rajputs at once set out against them, and, led by Prince Khoman of Chitor, finally expelled them from the sacro-sanct soil of India, A.D. 812. The Arabs were, in fact, at this time paralysed at the very centre of their power by the suicidal struggle ending, A.D. 750, in the extinction of the Hellenised Ommiades [saving the few who escaped into Spain, and renewed at Cordova the splendours of the Saracenic art of Damascus], and the transfer by the triumphant Abassides of the seat of the Caliphate to Baghdad, A.D. 763; a fatal error, for through it they lost touch with the stimulating West, and were brought completely under the debilitating and demoralising influences of the East; and were thus led on into abandoning the military defence of the Empire to mercenaries, until in the thirteenth century "the Caliphate of the East" found its dishonoured grave in "golden Baldac." For again the Scythians, now known as Turks and Mo(n)gols, - issuing forth, first as free-lances, and then as ravening conquerors, from the frost-bound steppes, and hills of ice, of the uttermost north, the Uttara-Kuru of the Hindus, once more swept away the undermined fabric of Semitic civilisation in Anterior Asia, and of Aryan civilisation in India and Eastern Europe—as though they had been but the glory of an hour. The Caucasian races have always rapidly spread themselves along the course, the "litus Aryanum" of the immemorial overland commerce between India, its perennial fountain-head, and Europe; and the great catastrophes of civilisation have resulted from the intersection of this line of human progress and culture by secular cataclysms of Negroes from Inner Africa into Hamitic Egypt, and of Turanians [in the phrasing of mediæval legends, the impure "Shut-up-Nations" of "Gog and Magog"] from Posterior Asia into Semitic Anterior Asia, and Hamitic Egypt, and Aryan India, and Persia, and Europe; isolating Caucasian civilisation in separate compart-

Hosted by Google

ments, from the Ganges and Indus to the Danube and Nile. And the pity of it is that these humanising nations have never since the time of Alexander the Great been again joined together in the same mind, and the same judgment, living in peace together, as men drinking from one "Loving Cup"; and armed with the omnipotence of their unity alike against the "Yellow Peril," and the "Black Peril." This is the unplotted tragedy of the Old World, on which the curtain has never yet been rung down.

II. THE AFGHANS.

The decline of the Arab Empire became manifest immediately after the death of Harun al Rashid, the contemporary and friend of Charlemagne, when one after another the provinces of the Eastern Caliphate began to throw off their allegiance to Baghdad. The Turkman, Ismail Samani, possessed himself of Transoxiana, Persia, and Afghanistan, setting up his throne in Bokhara. The fifth in descent from him appointed his "favourite" Turkman slave, Alptegin, Governor of Kandahar; where, on the death of his patron, he asserted his independence; leaving his kingdom on his own death, in 979, to his "favourite" Turkman slave and son-in-law, Sabuktegin. Jaipal, the Rajput Prince at Lahor, suspecting the designs of his minatory neighbour, resolved to anticipate them by himself seizing on Afghanistan; but, brought face to face with Sabuktegin at Lagman, on the road from Peshawur to Kabul, not far from Badiabad—where Lady Macnaughten and Lady Sale were held captive in 1842, a sudden storm in the mountains caused a panic among his superstitious warriors, and reduced him to the humiliation of purchasing his retreat by the surrender of his elephants, and the promise to pay a pecuniary indemnity. On the sinister advice of his Brahman priests, he deliberately broke his word of honour; when Sabuktegin, in his turn, marched off for Lahor, and, coming upon Jaipal on the plain of Lagman, inflicted a disastrous defeat on the unfortunate Prince; notwithstanding that his large army was now swollen by contingents from the allied Rajput States of Ajmir, Delhi, Kalinjir, and Kanauj.

The son of Sabuktegin, the fierce and avaricious bigot, "Mahmud of Ghazni," maintained the quarrel of his father, and in 1001 defeated Jaipal with frightful slaughter in the Peshawur ["Frontier-ward"] uplands; permitting him to return to Lahor only on the condition of paying an annual tribute to Ghazni. The disgrace of this was too bitter for the misguided Prince, who, after agreeing to the terms imposed on him, solemnised his death in accordance with the Rajput "office" of the *johur*. Mahmud's second expedition was against the Prince of Bathia [whose State is now included in the Pattiala State], and here also the Prince Bijai Rai, when he found his courageous resistance vain, committed the imperative sacramental suicide of the *johur*. Mahmud's fourth expedition, 1008, was directed to the destruction of the powerful league formed against him by Anandpal, the son of Jaipal of Lahor, and supported with passionate patriotism by all the noble Rajput ladies of Hindustan. For forty days the rival hosts confronted one another on the wide pavilioned plateau rising westward from Peshawur to the Khaibar Pass, and when a general action was brought on by an irresistible charge of Cashmerian highlanders, and Anandpal seemed to hold the winged victory in his outstretched hand, the elephant he rode in his lofty estate, took fright at "the Greek fire" used by the Mahometans, and the panic thus caused turned the battle in their favour; 20,000 of the flower of the Rajput manhood being left dead on the field. Then, pillaging on his way the fabulously endowed shrines of Nagarkot, now Kangra, Mahmud went back to Ghazni, to gloat at leisure over his abounding booty of "barbaric pearl and gold." His sixth expedition was undertaken for the sack of the yet holier and wealthier shrines of Staneshwara, "the Throne of God." In his seventh and eighth expeditions, 1014 and 1015, he ravaged Cashmere. His ninth expedition, 1017, he carried right into the heart of Hindustan, creeping stealthily along the slopes of the Himalayas, as near to the river sources as possible, and suddenly presenting himself with 20,000 Afghan infantry, and 100,000 Turkman cavalry before the gay and joyous garden city of Kanauj. The Rajput Prince at once capitulated; whereupon Mahmud, after three days' rest, hurried on to the great Bhramanical shrines of Mutra, the birthplace of Krishna, giving them up to fire and sword and rapine and plunder for twenty days; sparing only the fabric of a few of the temples, because of their exceeding beauty. His tenth and eleventh expeditions, of 1022 and 1023 respectively, were of comparative unimportance. The former was successful in its punitive object, the deposition of Jaipal II., of Lahor, for inciting a Rajput campaign against the Prince of Kanauj for his submission to Mahmud without an appeal to "the fortune of war." The

latter, directed against the Prince of Kalinjir, for assistance given by his predecessor to Jaipal I., of Lahor, against Sabuktegin, and by himself to Anandpal against Mahmud, proved unsuccessful. The twelfth, and last, and locally most vividly recollected of Mahmud's expeditions, was in 1024, when he trudged down across the sands of Sindh and Western Rajputana, a thousand miles to "the sack of Somnath" in Kathiawar. The Rajputs let him proceed on his outward march unmolested; but when he turned back, overweighted by the votive offerings of centuries, with his face anxiously set toward Ghazni, they dogged every turn of his flagging course through the desert wastes between the Luni and the Indus; leading him away from the sparse water-springs on the right hand and the left, and betraying him into every manner of ambages and ambuscades, until well nigh the whole of his bedraggled army was lost, and the greater part of his impious plunder. For the rest, he bilked the poet Firdausi ["the Paradisaic"] of his trivial pension [as others of us have been similarly bilked since then]; and in the very hour of his death wept on bidding farewells to his treasures of costly arms, and armour, and precious jewels; sternly controlling an occasional impulse to divide them among the loyal comrades of his retributive raids and other faithful friends. But he had a quick eye for great architecture; and, from a maze of squalid Turkman huts, he made Ghazni, with its "Palace of Felicity," and arcaded streets, and refreshing fountains, and its "Mosque of the Celestial Bride," the pride and boast of Central Asia. Therefore, one understands, after a passing emotion of amused surprise, the fitness of things in the fact that he died, if not exactly in the show and seeming, yet, and emphatically as regarded and judged by his contemporaries, in the full savour of sanctity. In a word, he was a man; and whatever he determined to do he did it right thoroughly. Furthermore, his fine feeling for architecture and for sumptuary objects of art, for all its taint of cupidity, must be accounted to him, and scarcely less than his leonine boldness, for the righteousness that exalteth a nation.

The First Afghan Dynasty, called of Ghazni, gave place, in the regular course of Afghan infamy, and perfidy, and treachery and murder, to the Second Afghan Dynasty, called of Ghor, 1153–1206; and Shahabudin, better known as Muhammad Ghori, succeeding to the *masnad* [the "cushion" and carpet throne of Mahometan rulers, Hindi, from the Arabic *sanada* "to lean against"], resolved on the conquest of Hindustan as a deliberate and definite policy. The moment was propitious for him. The Rathors of Kanauj had never been forgiven their ready surrender to Mahmud of Ghazni; and Ananda Deva, the Tomara Prince of Delhi, dying without male issue, and leaving his kingdom to Prithvi Raja, the Chauhan Prince of Ajmir, the latter, now uniting in his person the Tomara and Chauhan Rajputs, and the Sovereigns of Delhi and Ajmir, asserted his pretensions, against the prescriptive claims of [? his uncle] Jaya Chandra, the Rathor Prince of Kanauj, to be recognised as "the Over Lord," "Primus inter Pares," of the reigning Rajputs of Hindustan. This was bitterly resented by Jaya Chandra; who, taking advantage of the approaching marriage of his daughter, summoned all the Rajput Princes to be present on the occasion, and render him homage as their Lord Paramount. Prithvi Raja, who loved and was loved by his fair cousin, strong in his pride as in his affection, bluntly refused to demean himself as a vassal of Kanauj. Jaya Chandra, enraged, had an image of Prithvi Raja made in the garb of a door-keeper, and placed it at the entrance to the hall in which the nuptials of his daughter were to be celebrated. But he counted without the fair Sangagota, who, on approaching the hall, bearing the garland she was to place round the neck of the bridegroom selected for her, quietly turned, to the right and cast it over the head of the affronting image of Prithvi Raja. In a moment Prithvi Raja was at her side, and before the brilliant assemblage could recover from their amazement, had, with a sweep of his right arm, swung her up and across his saddle-bow, and galloped off with her, fast as his horse could bear them, all adown the rattling road to Delhi. It was Netherby Hall, and Young Lochinvar anticipated; and Sir Walter Scott was also there, in the person of Chand Bardai,* to immortalise the incident, so typical of the romantic and chivalresque life of the old Rajputs, "in Love and Arms delighting,"—in the "martiall *Pyrrhique* and the *Epique* straine" of the "Kanauj *Kandh*," or "Canto," of the *Prithviraj Chauhan Rasha*. Jaya Chandra, while sending his daughter her wedding trousseau [*jehaz*], called down on his son-in-law the wrath of the Afghans from Kabul and Lahor. Muhammad Ghori had, in

* The bard Chand actually flourished at this date; and although his authorship of the *Prithviraj Chauhan Rasha* has latterly been called in question, no reason whatever has been adduced for doubting the unhesitating tradition of the Rajputs on the point.

1191, made an attempt on Delhi, but being promptly met by Prithvi Raja west of the city, between Panipat and Staneshwara, the traditionary battlefield of the Kauravas and Pandavas, he was there well defeated. But now, 1193, having strongly recruited his Turkman cavalry, he at once called them "to boot and saddle," and set off again for Delhi, with an invincible force. Betrayed by Jaya Chandra, and deserted by the Bhagela Rajputs Princes of Gujarat, yet supported by the Gehelot Rana of Chitor, Prithvi Raja was able to muster some 200,000 "cavaliers," and a proportionate number of "men-at-arms" to his colours. The two hosts came in sight of each other from the opposite banks of the River Sarasvati; Prithvi Raja having again chosen his ground, "the Field of the Kuravas and Pandavas" at Staneshwara, because of its auspiciousness among all Hindus, and its good omen for himself also. But the time passed by the Afghans in preparations for the coming battle, was wasted by the Rajputs, who trusted to the charmed ground whereon they camped, in athletic sports and feasting; when, one night, just before the dawn, Muhammad Ghori, crossing the Sarasvati, suddenly awoke the day with his drums and trumpets, and was upon the Rajput host before his approach had been observed. Prithvi Raja, however, soon got his army in hand, and was apparently pressing Muhammad Ghori to a second defeat, when the latter, feigning a general retreat, and the unsuspecting Rajputs—true Aryas in this respect—falling into the flagrant confusion of a reckless pursuit, he at once charged them with the whole élite body of his hitherto masked cavalry, called up from the right and the left against the heroic Prithvi Raja. For miles "the stricken field" was strewn with cast-away flags, and spears, and shields, and heaped bows and jeweled swords, and plumed casques, and gauntlets, greaves, and breastplates, exquisitely chiselled, and damascened, and gaily dyed scarves, all commingled with the blood of the countless dead. For it was not only the number of the dead that lay there that was so portentous of evil to come, but their position, their power, and their princely worth. Prithvi Raja, fighting to the last, his sword still in his hand, refusing all surrender, although surrounded on all sides, and virtually a prisoner, was cut down in cold blood. His youthful bride immolated herself on his funeral pyre. The Prince of Chitor shared in his death; and with them also fell 150 of the purest and best "bloods" of all the Rajput nobility of India. It was the Flodden Field of Rajasthan; and for 600 years India, India of the Hindus, never recovered from that "doubly redoubled" deadliest stroke of doom; not until England stepped forward to revindicate her Aryan liberties from Turanian slavery and oppression. Storming Ajmir, and massacring its garrison, Muhammad Ghori, in 1194, passed on to Kanauj, which fell an easy prey to his arms; most of its defenders being driven into the Jamna, with the brave old Jaya Chandra at their head, "bearing up their chins" to the last. When recovered his body could only be identified by his case of false teeth, held together by gold wire.

In the dramatic contrasts of its opening and closing scenes, surely never was a tragedy, not even of "the House of Atreus," of deeper or more moving woe. It is the story of Juliet and her Romeo, but involving in the pathetic fate of these Rajput lovers the doom of a great mediæval Aryan Empire; presenting Aryan civilisation and Aryan culture in a brighter, happier—because more natural—and simpler form than it had taken since the days of Alexander the Great, or will ever take again, for it was still Greek in outward form as well as in its sentiment and vitalising spirit. No wonder that the story inspired Chand Bardai to sing his undying requiem of the Rajput race.

The scattered remnants of the reigning families retired through the defiles of the Jamna into the sequestered recesses of the Aravali Hills, and the even more secretive solitudes of the salt desert between the Luni and the Indus; Rao Sivaji, the grandson of Jaya Chandra, settling in Marwar, with his capital at Mandor.

The conquests of Gujarat, Oudh, Bengal, Bahar followed, and by 1206, the date of Muhammad Ghori's assassination, the irregularly and loosely organised rule of the Afghan Mahometans extended over all Hindustan, or India north of the Tapti and Nerbudda Rivers, and the Satpura and Vindhya Mountains.

On the death of Muhammad Ghori, one of his "favourite" slaves seized on the government of Afghanistan; and another, his ablest general, Kutubaddin, on that of Hindustan, and founded the Third Afghan Dynasty of India, called of "The Slave Kings," 1206–88, with their throne at Delhi; where the Kutub Minar commemorates his name. During the reign of his successor, Chinghiz Khan appeared on the banks of the Indus, and again between 1246 and 1266; and during the latter period an embassy was sent to Mahmud II., the eighth of "The

Slave Kings," from Hulaku Khan, the destroyer of Baghdad, a grandson of Chinghiz Khan, and brother of Kublai Khan "in Xanadu." However, the only events of this period directly connected with Rajputana were the capture of the hill fort of Rintambor in the Jaipur State, and a rising of the Princes against Balin, the ninth "Slave King," 1266–88, said to have been quelled in an immense slaughter of the Rajputs.

The Fourth Afghan Dynasty of India, called "The House of Khilji," was founded on two assassinations by the Khilji chieftain Jelaluddin in 1288. He was succeeded, after the assassination of his two sons, by his nephew Allauddin Khilji, "The Sanguinary," whose reign is memorable for a great raid of the Mo(n)gols on Delhi, 1298; and for the commencement of the regular subjugation of the Dakkan and the Carnatic. Risings of the Rajputs were put down by the reduction of Gujarat, 1297, the capture of Jeisalmir in 1294, the recapture of Bintambor in 1300, and the siege and sack of Chitor, 1303–5. The Gehelot Prince, driven to despair, resorted to the awful rite of the *johur*. His queen, Padmani, a woman of notable beauty, with all the ladies of the Court, and the wives of the warriors, built up a vast funeral pyre in the centre of the city, and "so passed, as in a chariot of fire, to the Heaven of Indra"; and all the men rushed out through the gates upon the besiegers, who cut down the most of them on the spot, a few only escaping into the overhanging Aravali Hills. This is "the First Sack of Chitor," of the three great "sacks" of that city. With the poisoning of Jelaluddin by his "favourite" slave and trusted general, Malik Kafur, and the murder of his third son and successor by his own "favourite" minister, a vile *parvari* [compare the Greek πάροικος, "parishioner"], an outcast from Hinduism, and a pervert to Islam, the House of Khilji came to its hideous end in 1321.

The Fifth Afghan Dynasty in India, called "the House of Tughlak," from its founder, Gheiazuddin Tughlak, Governor of the Panjab, the son of a Turkman slave by a Jat mother, reigned in a succession of seven kings from 1321 to 1412. This period is marked by the rebellion of the Mahometan Governors of the Provinces of the Empire against the central authority at Delhi, and by the terrifying advent of Timurlangra, "Timur-the-lame," "Great Tamburlame," at Attock, September 1st, 1398. He swept through Hindustan like a devastating whirlwind; and, on being proclaimed Emperor at Delhi, after massacring 100,000 prisoners in cold blood, in jubilation over the occasion, and going in state to the noble mosque of polished white marble on the banks of the Jamna, "to render to the Divine Majesty his humble tribute of fervent praise for the signal honour done him," he recrossed the Indus, in March, 1399, in the same unexpected way as when he entered India just six months before; taking with him the massed, incomputable, and incomparable pillage of Delhi, Mirut and Hardwar.

The Sixth Afghan Dynasty, called "The Four Seiads," 1414–1450, ruled at Delhi as Viceroys of the Mo(n)gols; and the Seventh, called "The Three Kings of the House of Lodi," 1450–1526, was the last of the abhorred Afghan dynasties of India. Altogether, they had torn and battened on India, like devouring dogs, 320 years.

III. THE MO(N)GOLS.

The Afghan Governor of Lahor, himself a Lodi, having revolted from Ibrahim Lodi, the last of his dynasty, called in the aid of Zahiruddin Muhammad, surnamed Babar ["Baber"], "the Lion Hearted," hereditary Khan of Kokan. He was the sixth in descent from Timur, and, on his mother's side, a descendant also of Chinghiz Khan. Having occupied Kabul in 1504, and Kandahar in 1522, he readily responded to the invitation of Daulat Khan Lodi; his first act, after crossing the Indus, being to seize and depose the disloyal Daulat Khan, as an untrustworthy person to leave on the line of his communications with Central Asia while on the march to Delhi. Baber had only 20,000 men with him, but mostly Turkman cavalry; and when he found himself barred at Panipat by Ibrahim Lodi with an army of 100,000 men and 1,000 elephants, he at once extended himself, masking his cavalry on both flanks. He let Ibrahim Lodi exhaust himself in repeated attempts to rush the position, and then, at the psychological moment, slipping his élite cavalry on the disordered Afghan host, and assailing them on the right hand and the left, he struck down 5,000 of them on the spot, with Ibrahim Lodi in their midst. The rest of the rout, recoiling before his solid assault, like surging waves from a rock-bound shore, were rolled back in a headlong flight, and torrent of bloodshed, into the swift flowing, unheeding stream of the Jamna. In suchwise, on April 19th, 1526, was the second of "the Four historical Battles of Panipat" won and lost. The capture of Agra [compare "ager," a "field"], imme-

Hosted by Google

diately followed. Henceforward, throughout the rule of the Mo(n)gol Emperors of Delhi [1526–1806, and nominally to 1857], the history of Hindustan passes into the open light of our own day, and need be no further traced here beyond its points of contact with the history of Rajasthan, as now contracted into Rajputana.

Neither the Afghans nor the Rajputs anticipated that Baber would remain in India after the plunder of Delhi and Agra. They expected that he would return like Timur, with the bloated burden of his bag and baggage, into Central Asia. He had, however, resolved to govern India in India; and forthwith set about the supersession of the rebellious Provincial Governors of the Lodis, and the resurgent Rajputs; entrusting this arduous duty to his eldest son and successor, Humayun. The Rajputs, when they found that Baber had come to stay among them, at once rose against him, in a last desperate effort to restore the *Kshatriya* supremacy throughout Hindustan. They were led by Rana Sanga the *Kalas* [compare "cœlus"], "the Pinacle—of glory" of Chitor, and the Rai of Jaipur, and the Rao of Jodhpur, and Medni Rai, a brave and enterprising Rajput cadet, who had recently possessed himself of the fortress and territory of Chanderi in Malwa. This patriotic league was shattered at a blow at the battle of Sikri—afterward called by the Mahometans Fatehpur, the "City of Victory"—February, 1527. Shortly after this, Bahadur, the Sultan of Gujarat, invaded Mewar, and storming Chitor, 1532, "the Second Sack of Chitor," the noble Rajput queen before celebrating the *johur* sent her bracelet to Humayun, to pledge him by this immemorial Rajput token of adopted brotherhood, to the protection of her son. The magnanimous Mo(n)gol at once marched against Bahadur, and drove him back into Gujarat. But Humayun, although brave and generous, was unenterprising, and was never free from troubles with the Afghans for the fifteen years of his reign, 1540–1555–6.

Jellaluddin, surnamed Akbar, "the Great," the son of Humayun, was, throughout his reign, 1556–1605, the contemporary of Queen Elizabeth, 1558–1603. He, or rather his faithful guardian and great general, Beiram, stamped out the Afghans, now led by a great *Kshatriya* general, Hemu, on the plain of Panipat, November 5th, 1556, "the Third Battle of Panipat"; and the following six years, 1567–73, were spent in the reduction of the again resurgent Rajputs. The first to submit was Bahara Mal of Amber [Jaipur], one of whose daughters had been taken in marriage (? 1561) by Akbar; and the daughter of whose son, Rai Bhagvandas, was married (? 1585) to Selim, the son and successor, under the name of Jehanghir, "the World Conqueror," of Akbar. Again, on the submission of Jodhpur in 1573, Rao Udai Sing gave up his sister Jodha Bai in marriage to Akbar. Raja Man Sing, another brave and ever faithful general of Akbar, was a member of the reigning family of Jaipur; and another *Kshatriya* Jodai Mal, distinguished as a general, was also a distinguished financier, and the greatest of Akbar's ministers. The great Emperor's employment of *Kshatriya* Hindus, in this way, in high office, and responsible military commands, served greatly to reconcile them to the rule of the Mahometans; and his marriages with the Rajput princesses also undoubtedly improved the physical vigour and the intellectual power of the offspring of "the Great Mo(n)gols," and tended to ameliorate the religious and social prejudices separating Mahometans and Hindus. But, at the time, the Houses of Jodhpur and Jaipur incurred much odium and contempt for permitting these family alliances. The Rana of Chitor resolutely refused to acquiesce in the degradation, as he regarded it, and defied the wrath of Akbar against his proud and scornful contumacy. He preferred death to what he deemed, and was deemed by all his peers, to be dishonour, and the foulest dishonour. Akbar accordingly laid siege to Chitor; when, there being no hope of deliverance, the *rani* solemnised the rite of *johur*. This is known as "the Third Sack of Chitor," 1567–68. Udai Sing, the Rana, on the approach of Akbar, leaving the defence of the city to Jai Mal, the Chief of Bednor, had sought refuge in the neighbouring forests, where he afterwards built the city of Udaipur; making a vow that so long as Chitor remained a ruin, neither he, nor his successors, would twist their beards in the Rajput fashion, or eat or drink from anything but leaves, or sleep on anything but straw; and to this day the Ranas of Udaipur sleep on sumptuous beds *laid on straw*, and eat from golden and silvern plates *laid on green leaves*, and never twist their beards.

By 1592 Akbar had made himself master of Hindustan, keeping a strong hold on Afghanistan, as the key to the plains of the Indus and Ganges; and he now commenced operations for the recovery of the lost Dakkan to Islam. But in 1601 his health seriously failed him,

Hosted by Google

and the last five years of his life were overshadowed by the gloomiest forebodings for the future. He knew that he was a man superior to all the men about him; that there was none to carry on his work, that there was not one that even understood its full significance. He died in absolute mental isolation,—like that of the lonely eagle in its solemn flight at sundown to its upland arie. In truth he was not only the Greatest of "the Great Mo(n)gols," but pre-eminent above all his pre-eminent contemporaries in Europe; an ornament and pride not only of Islam, but of the human race. His transcendent name in India not so much rests on his conquests, as on his genius in consolidating them, and creating the organisation for their civil administration and military defence. He freely bestowed, or rather he enforced, religious toleration on his subjects; and could he have had his will of their hearts he would have broken down all social barriers between them. He advanced Hindus not only to the highest and most dignified, but to the most responsible and confidential appointments in the State: and never should it be forgotten that they served him with scrupulous and whole-hearted fidelity, and that the very loyalest of them were the strictest and most uncompromising devotees of their own religious beliefs and observances. He abolished the infamous poll tax on Hindus, he forbade *sati* ["suttee"], and encouraged the remarriage of Hindu widows. He severely repressed the attempts of the Rajputs to act independently in matters of high policy and State necessity; but so long as they were submissive in their political relations with the Paramount Power he not only respected their social prejudices, and sympathised with their misfortunes and aspirations, but treated them as valued and honoured and trusted friends; and he made the most advantageous uses of them for the purposes of imperial defence; not attempting to dragoon them into uniformity with the Mo(n)gol drill-books, but leaving them in their own national military formations, racy of the soil, as volunteer troops, who above all, horse and foot, were, every one of them, a gentleman, as it was of olden days with the Scots clansmen. He never interfered in any way in the internal economy of their sovereign States; and he never, in the benign intelligence of his capacious brain, conceived the thought of forcing an alien system of education on a people who, through at least 2000 years of history, had elaborated the most perfect type of Aryan speech, and created a splendid literature, and unique architectural and industrial arts of their own, and a highly spiritualised idiosyncratic religious culture. We may therefore the better understand the anguish of his dying years, 1603–6; the daily failing of his great heart for fear, and for looking forward to the evils that he saw were coming on the Mo(n)gol Empire when his own fate was fulfilled. He was constantly speaking to his family and his great nobles of the inevitable consequences of their mutual jealousies and rivalries, and of the imminent dangers of persisting in them; and exhorting them to concord and frank co-operation. But they were as words spoken to the wind that bloweth where it listeth: while at this very time, February of 1601—

"Riding in *Thames*, between *Lymehouse* and *Blackwall*," were the "Hector," "Ascension," "Susan" and "Guift," with the "Red Dragon" of the "First Voyage" of the first East India Company, freighted with the "unshunable destiny" of the English race in Asia; those who turned a deaf ear to the warnings of Akbar little witting that they were thus already preparing the way before it.

(To be concluded.)

AGRICULTURAL ASSOCIATION AMONG THE MOHAMMEDANS OF THE MAGHREB (MOROCCO, ALGERIA, TUNIS).*

The vast Colonial Empire of France in North Africa awaits its full development chiefly from the progress of agriculture: together with the factors of technical order, factors of an economico-social order also here assume constantly increasing importance, the relations between the land and man, the relations between the various agricultural classes, between the natives themselves, and between these and the colonists.

An article in the June number of the *Bulletin of Economic and Social Intelligence*, published by the International Institute of Agriculture, gives, as summarised from a learned work recently published by Louis Milliot, a brief indication of the character of these relations as they appear in the religious law of the Mohammedans and in their civil law, and of the forms in which they have asserted themselves throughout the various civilisations introduced by conquerors: in a word, of the characteristics and development of agricultural association among the Mohammedans of the Maghreb from the ancient family community to the modern forms of co-operation. It is well known that in the Mohammedan world the religious element

* Summarised from the *Bulletin of Economic and Social Intelligence* of the International Institute of Agriculture, Rome. Year III., No. 6. June, 1912.

Hosted by Google

exercises absolute sway over all the manifestations of public and private life: thus law becomes confused with religion.

By the side of the religious law, however, under the pressure of new needs, a civil code has been formed which is often in conflict with the religious. This dualism is met with specially in connection with association, and the *fiqh* (religious law) has often had to give way before the *urf*.

Thus the severe prohibitions and limitations impeding the free development of the forms of association, which may be summarised under the heads of *usury* and *hazard*, were in practice relaxed so as to allow of the development of new types of association.

The four typical forms of agricultural association recognised as lawful by the religious law, but always surrounded by a series of restrictions, are the following: the *muzârâ'a*, or contract for collective sowing and cultivation; the *musâqâ*, or contract for collective irrigation; the *mughârasa*, or planting contract; and the society for livestock improvement. These contracts have in practice gradually been freed from their trammels, and have given birth to new accessory forms, from the society for grafting trees to that for the herding of animals. Further, while in religious law only societies aiming at profits were met with, in the law in common use many forms have appeared approaching to our agricultural associations, for collaboration and assistance, such as the co-operative *silos*, and the societies for rendering mutual service.

The society most frequently met with among the agricultural population of the Maghreb is the *kammâsâ* (society on the basis of a fifth of the profits), which is a form of the *muzârâ'a*: one of the members (the *fellah*) provides the land, the stock, the seeds, etc., the other (*kammas*) the labour. The latter receives a part of the crop, generally a fifth. Then come the *msaqa* and the *mgharsa*: the first extends to trees, cereals, vegetables, etc.: the *fellah* provides the land, the seed, the capital, the *kammas* the labour, especially for irrigation, and receives the half or the third, and sometimes, as in the case of date palms, the eighth of the yield. In the second (*mgharsa*), the proprietor places his land at the disposal of a partner for the plantation of trees, especially olive trees, on the condition that within a fixed time the ownership of a half or a third part of the trees and the soil shall pass to the latter.

The French conquest gave a violent shock to the primitive *régime* of the Maghreb, and hence also to the system of agricultural association: the era of peace and security introduced into the country has, on the one hand, relaxed the bonds between *fellah* and *kammas*, so that the latter has been transformed into a simple *métayer*; on the other, the increase of the native population, the absorption of the soil by Europeans, the reforms in the land system facilitating the sale of lands and the abolition of imprisonment for debt, have led to many *fellaheen* being reduced to the *kammas* class and others becoming labourers on wages, thus increasing the mass of the proletariat. This phenomenon has aroused a certain anxiety for the future of those regions; and the Government has sought how to restore among the natives, by means of special facilities and encouragements, the spirit of association and the old forms of societies best adapting themselves to the times, besides introducing those mutual and co-operative systems which have given good results in the mother country. So, for example, it has been attempted to introduce into every commune or *caidat* native thrift, mutual aid and loan societies, as developments of the ancient collective granaries: in Algeria there are to-day about 200 of these, with more than half-a-million members and 19 millions of capital, and in 1907–08 they gave loans for 9 millions for purchase of seeds, cattle, etc., at the rate of 5 per cent. for an average term of from three to eight months.

There have further been founded agricultural credit banks, mutual labour societies, and irrigation syndicates, which have given excellent results.

Private initiative at last has, on its side, promoted the foundation of various forms of societies, agricultural syndicates, co-operative societies for production, etc. Among others, the experiment of the "Setif Agricultural Comice" (Constantine), of native co-operative societies for the cultivation of lands conceded or leased deserves mention. Association, then, is destined to accomplish an important work in the agricultural economy and policy of French North Africa.

THE VANILLA INDUSTRY OF THE SEYCHELLES.

In the preparation of vanilla beans in the Seychelles, a successful result depends on the pods being picked at the right stage of maturity more than on anything else—that is, when they are ripe and just before they begin to split. An unripe pod will never prepare well, and is always inclined to become mouldy; split or over-ripe pods have lost much of their value. A pod in condition to be picked has lost to a great extent its shiny green colour, has become duller, with an almost silvery appearance. The longitudinal lines along which it will eventually split, if left, are distinctly marked. The tip is light in colour, or even yellowish, and comes away fairly evenly from the stalk when broken off. Pods in a bunch seldom ripen simultaneously, so they must be carefully watched. When brought in, the pods are sorted into five qualities—(1) over six inches long; (2) over four inches long; (3) under four inches long; (4) split; (5) unripe, broken, etc. A vessel of water is heated to 188·6° F.; the pods are placed in an openwork basket, and dipped for ten seconds, withdrawn, and allowed to drain for about five seconds; dipped again for ten seconds, withdrawn, and drained as before; dipped again for about five seconds, or until their colour has changed to a dark green. Large pods require

Hosted by Google

a longer third dipping than small ones. After being scalded, the pods are wrapped in woollen blankets and left in a warm, dry place for twelve hours, when they have taken on a blackish hue. They are then placed in trays in a room heated to between 90° and 100° F., on one thickness of blanket, and covered by another. In about ten days the largest pods will have become wrinkled, the smaller ones before that. When in this state they can be removed to a cool drying room, where they are placed on trays uncovered, heaped on each other to a depth of three inches, and turned about every day. The more slowly vanilla is dried the better. When the pods are dry they are taken out and stored in a dry place in wooden boxes. They are examined thoroughly from time to time, to see that they show no signs of mould. A dry pod should have a silky feeling, the wrinkles must be soft, there must be no hard centres, and it should be possible to tie the pod in a loose knot without breaking it. Absolute cleanliness is observed all through the preparation, and those who handle vanilla are careful to wash their hands before touching it. When sufficiently dried, the pods are put into a vessel containing water at a temperature of about 80° to 90° F., and stirred with the hands for about five minutes, then taken out and placed in trays or on a blanket in the sun, where they soon dry. The pods are now measured and tied in bundles of sixty pods each, with two turns of flax thread in the middle only. Tin boxes are used in the Seychelles, thirteen inches long, nine inches broad, and six inches deep, a lining of parchment paper being placed in each. The vanilla must be packed fairly loosely, and the lid secured by solder.

THE PRODUCTION OF TALC IN THE UNITED STATES.

A new record was established in the United States in raising the annual production of talc or soapstone in 1910 to 150,716 tons, an increase of 16 per cent. in quantity, and 30 per cent. in value, compared with the production in 1909, according to a report issued by the Geological Survey in that country. There were eleven producing States—California, Georgia, Maryland, Massachusetts, New Jersey, New York, North Carolina, Pennsylvania, Rhode Island, Vermont, and Virginia. The increase in production was chiefly in New York, whose output of 71,710 tons formed nearly half of the total production of the country. Talc is usually marketed as rough from the mine, sawn into slabs, and made up into manufactured articles, such as laundry tubs, or ground into powder. In 1910, 69 per cent. of the talc was ground, and 21 per cent. made into slabs and manufactured. The product of New York is practically all ground. Vermont ranks second, and produces both ground talc and soapstone. Virginia, the third in rank, produces some ground talc, but a large amount of soapstone, in the production of which it outranks all other States. Most of the ground talc is used in the manufacture of various kinds of paper. It finds application also in the manufacture of moulded rubber forms, and as foundry facings, and paints. It readily absorbs grease, and is used to remove spots from silk, and to bleach various articles. On account of its peculiar properties, it is widely used to lessen friction, and for this purpose it is dusted into gloves and shoes, and blown into conduits to ease the application of electric wires, or other conductors. One of its widest applications is in toilet powders, most of which are made from the finest talc imported into the United States from Europe. Laundry tubs, griddles, foot-warmers, and many other similar utensils are manufactured from soapstone. The higher grades of massive talc, free from flaws, are sawn up to make pencils or crayons, French chalk, and other special articles.

NOTES ON BOOKS.

Seasonal Trades. By Various Writers. Edited by Sidney Webb, LL.B., and Arnold Freeman, M.A. London: Constable & Co., Ltd. 10*s*. 6*d*. net.

At the London School of Economics and Political Science an advanced class of social investigation and research is conducted by Mr. Sidney Webb, with the assistance of Mr. Arnold Freeman. The students are taught to use the different methods of investigation and the principal sources of information, and are expected to write theses or monographs on the special subjects which they have been studying. The general subject investigated last year was "Seasonal Trades in the United Kingdom." Various trades were studied by different students, and in the present volume we have a series of monographs on seasonal trades in general, the tailoring trade in London, the waiter, the cycle industry, the gas industry, the London millinery trade, the skin and fur trades, the boot and shoe trade, and the building trade. Although these chapters of "students' work," as Mr. Webb calls them, prepared amid the stress of examination and other pressure, fall short of the highest standards of scientific investigation or economic scholarship, they represent, as he claims, a considerable amount of patient, original, and independent research, and contain a great deal of really valuable information.

But perhaps the most interesting, if the briefest, portion of the book is the preface by Mr. Sidney Webb, in which he points out that though each particular trade may be seasonal, still, "taking all the industries of the United Kingdom together, there is no such striking difference in the total volume of employment from one month to another as is commonly supposed." The statistics of the Board of Trade show that if there is no month in the year when some great industry is at its slackest,

Hosted by Google

there is also no month in the year when some great industry is not at its busiest. Thus, while January is the worst month in iron-mining and the furnishing trades, it is the busiest at the docks of London, and one of the busiest for coal-mining; in February the plumbers suffer most from unemployment, but it is the best month for the paper-makers; March and April are bad months for the coopers, but the best for steel-smelters and the textile and furnishing trades; and so on through the whole tale of the months. To sum up in Mr. Webb's own words, "there is, in the United Kingdom of to-day, no seasonal slackness in the community as a whole." From this he draws the conclusion that the seasonal alternations of over-pressure and slackness, which press so disastrously on many classes of workers, are not inevitable in the nature of things, but are "due only to failures of adjustment .... They mean only that our statesmen have not yet given themselves the trouble to make the social adjustments and to employ the various devices by which these calamitous dislocations of the lives of so many hundreds of thousands of households can be prevented."

As to the nature of these adjustments and devices the present volume says little, nor does Mr. Webb think it the duty of his seminar to discover any practical plan for preventing seasonal unemployment. He is concerned at present with training investigators who will be able to study the causes, and this is obviously the first step towards any satisfactory solution of the problem.

Victoria and Albert Museum: Review of the Principal Acquisitions, 1911. London: His Majesty's Stationery Office. 1*s.*

Up to the present an occasional announcement in the press has been the only intimation received by the public of fresh objects acquired by the museum; but the Board of Education have now been fortunately inspired to follow the example of many foreign museums, and to issue an annual review of the principal acquisitions during the period. This volume is the first of the series. The descriptions of the objects are arranged according to the departments to which they respectively belong, viz., Architecture and Sculpture, Ceramics, Engraving, Illustration and Design, the Library, Metalwork, Paintings, Textiles, Woodwork, and the Indian Section. In each case the descriptions have been prepared for each department by the officer in charge of it, and a number of excellent illustrations add much value to the written accounts.

It is gratifying to learn that the list of private benefactors for 1911 is unusually long, especially as in the future, in the opinion of Sir Cecil Smith, the museum, if it is to keep pace with its requirements, will have to depend more and more on the good will of private individuals.

The book is excellently printed, and the Board of Education are to be congratulated upon their new departure.

GENERAL NOTES.

Electric Lamps for Miners.—The awards have been issued in the competition, announced by the Home Office in May, 1911, for a prize of £1,000 for the best electric lamp suitable for miners. The prize money was provided by a colliery owner, and the competition was open to persons of any nationality, conditions being laid down that the lamp must be safe, efficient, convenient, and durable, as well as economical in first cost and use. Mr. Charles Rhodes, a past President of the Institute of Mining Engineers, and Mr. Charles H. Merz, who served on the Departmental Committee on the Use of Electricity in Mines, acted as the judges. The first prize has been awarded to the C.E.A.G. lamp sent in by Mr. F. Farber, Beurhausstrasse 3, Dortmund, Germany, who will receive £600; and sums of £50 each have been apportioned to the following competitors, whose lamps are stated to "possess considerable merits":—Thomas Attwater, 22, Pelham Square, Brighton; Adolf Bohres, Zietenstrasse 12, Hanover, Germany; Bristol Electric Safety Lamp Works, 40, Great Smith Street, S.W.; The Electrical Company, Ltd., 122–124, Charing Cross Road, W.C.; W. E. Gray, 19, Archer-street, Camden Town, N.W.; H. F. Joel, 134B, Kingsland Road, N.E.; Oldham and Son, Denton, Manchester; Tudor Accumulator Company, 119, Victoria Street, S.W.

The Iron and Steel Institute.—The autumn meeting of the Iron and Steel Institute will be held at Leeds, from September 30th to October 4th, 1912. The provisional list of papers expected to be submitted is as follows:—(1) "On Nitrogen and Iron," by J. H. Andrew (Manchester). (2) "On the Solubility of Cementite in Hardenite," by Dr. J. O. Arnold (Sheffield) and L. Aitchison (Sheffield). (3) "On the Solubility or Diffusion of Hardenite in Ferrite," by Dr. J. O. Arnold (Sheffield) and C. Chappell (Sheffield). (4) "On the Gases Evolved on Heating Steel to its Melting Point in a Vacuum," by G. Wesley Austin (Birmingham). (5) "On Allotropy in General and that of Iron in Particular," by Dr. C. Benedicks (Stockholm). (6) "On a New Type and Method of Construction of Large Gas Engines," by A. E. L. Chorlton (Manchester). (7) "On the Thermal-Magnetic Transformations of 25 per cent. Nickel Steel," by Dr. E. Colver-Glauert (Sheffield) and Dr. S. Hilpert (Charlottenburg). (8) "On a new Method for the Improvement of the Soundness of Steel Ingots by the Aid of Thermit," by Dr. Hans Goldschmidt (Essen/Ruhr). (9) "On a Method of Producing Sound Ingots," by Sir Robert A. Hadfield, F.R.S. (Sheffield). (10) "On a New Method of Revealing Segregation in Steel Ingots," by Sir Robert A. Hadfield, F.R.S. (Sheffield). (11) "On the Magnetic Properties of Manganese and Nickel Steels," by Dr. S. Hilpert (Charlottenburg) and Dr. W. Mathesius (Worcester, Mass., U.S.A.). (12) "On the Question of the Existence

Hosted by Google

of Commercial Hyper-Eutectic White Iron Free from Manganese," by Dr. H. M. Howe (New York). (13) "On Steel Works Yields," by P. Longmuir (Sheffield) and W. H. Robinson (Sheffield). (14) "On Some Aspects of Wire Drawing," by P. Longmuir (Sheffield). (15) "On the Manufacture of Open-hearth Steel, with reference to Improvement in Yield," by F. W. Paul (Glasgow). (16) "On Rolling-Mill Practice in the United States," by J. Puppe, D. Ing. (Breslau). (17) "On the Growth of Cast Irons after Repeated Heatings, Parts V. & VI.," by Professor H. F. Rugan (New Orleans, U.S.A.). (18) "On the Iron Ores and Mineral Resources of Chili," by Charles Vattier (Santiago, Chili).

Silk Harvest in Piedmont, 1912.—This year's silk harvest in Piedmont, although slightly better than that of 1911, was still inferior to those of former years. The average production of cocoons during the last five years has been 4,757,454 kilogs (10,490,156 English lbs.) annually. Since 1908, the production of silk cocoons every year has been:—

	Weight of Cocoons.	
Year.	Kilograms.	English lbs.
1908	7,048,270	15,541,435
1909	4,040,090	8,908,398
1910	4,837,760	10,667,260
1911	3,797,080	8,372,561
1912	4,064,070	8,961,274

This enormous decrease in the annual production for the last four years must be attributed mainly to the disease of the leaf of the mulberry tree, *diapsis*, in consequence of which many landowners and farmers have been forced to discontinue the cultivation of the tree. The scarcity of the leaf, together with the present high rates of wages in the north of Italy, also have tended to discourage the rearing of silkworms in Italy generally.

Railway Construction in Tripoli.—The *Rivista tecnica delle Ferrovie Italiane* states that much activity is being displayed in railway construction just now at Tripoli. The short line along the coast to Gargaresch is to be pushed forward further west as far as Zanzur. The first section from Tripoli to Gargaresch, which has been opened already some months, is rendering good service not only for the conveyance of troops and military stores, but also for the transport of the stone required by the contractors for the harbour works at Tripoli and for the building of the walls round the town. A locomotive shed, workshops for repairs, and sidings for connecting the line with the port have also been completed. A regular service of trains has been established on the branch line, which runs in a south-easterly direction to Ain-Zara. The journey, including stoppages at the junction station at "I Fornaci" and at the cavalry barracks, occupies about three-quarters of an hour. The works of a third line running east from Tripoli to Tagiura are also in hand, and will be shortly completed.

Highest Road for Autocars in Europe.—The highest road in Europe on which a regular summer service of autocars is now running is probably the "Grande route des Alpes," which unites the shores of the Mediterranean and the Lake of Geneva. Leaving Nice, this road crosses, via Barcelonnette and Briançon, the Maritime and Alps of Dauphiné into Savoy, reaching the station of St. Michel de Maurienne at a level of 712 metres (2,338 feet) above the sea. From St. Michel, which is the frontier station at the north end of the Mont Cenis Tunnel, Chambery and Geneva can be easily reached by road or rail. The following are the altitudes of the principal mountain passes by this route:—

	Above sea-level.	
	Metres.	Feet.
Col St. Michel (Dept. Basses Alpes)	1,505	4,938
Col d'Allos	2,251	7,383
Col de Vars	2,115	6,937
Col d'Isoard	2,388	7,832
Col du Lautarat	2,058	6,750
Col du Galibier	2,658	8,718

Compared with some of the better known carriage roads in the Alps, the Col du Galibier, which divides Dauphiné from Savoy, is lower than that of the Stelvio, which is 9,155 feet above the level of the sea, and higher than the Mont Cenis (7,894 feet), the St. Gothard (6,935 feet), the Simplon (6,590 feet), or the Splugen (6,945 feet).

Price of Frozen Meat at Milan.—The present prices for frozen and chilled beef from Argentina at the cold storage warehouses of the importers at Milan, are quoted as follows:—

	Per 100 kilogs.	Per English lb.
Frozen Beef.		
Forequarters	70 to 73·50 lire	= 3·18*d.* to 3·53*d.*
Hindquarters	91 to 93·50 lire	= 4·13*d.* to 4·36*d.*
Sides	82 lire	= 3·72*d.*
Chilled Beef.		
Forequarters	93 lire	= 4·20*d.*
Hindquarters	101 lire	= 4·58*d.*
Sides	97 lire	= 4·40*d.*

Customs and town duties (*dazio*) are not included in the above prices, which are wholesale.

Manufacture of Camembert Cheese in Canada.—A French trade report states that the production of soft cheeses, especially the Camembert, is becoming an industry of considerable importance in Canada, which country may in the near future prove a formidable rival to France, especially in the American market. One factory alone at Wendover is turning out no fewer than 5,000 Camembert cheeses per day. This output, when the extensions now in progress are completed, will be tripled. The Camembert cheese made in Canada is cheap, and is much esteemed in the United States. There being no dull season in cheese-making, the dairy farmers find a constant and steady demand for the produce of their cows all the year round at remunerative prices from the cheese makers.

FRIDAY, AUGUST 30, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICE.

EXAMINATIONS.

The examinations for next year will commence on Monday, April 7th, 1913. The full time-table was published in the *Journal* of the 16th inst.

The examinations are arranged under the following stages: — Stage I. — Elementary; Stage II. — Intermediate; Stage III. — Advanced.

The subjects include: — Book-keeping, Accounting and Banking, Shorthand, Typewriting, Economics, Précis-writing, Commercial Law, Commercial History and Geography, Arithmetic, Business Training, Handwriting, Modern Languages, and Music.

In the Advanced and Intermediate Stages, First and Second-class Certificates will be granted in each subject.

In the Elementary Stage, Certificates will be given in each of the subjects enumerated. These will be of one class only.

Certificates of proficiency will be granted in each stage to Candidates who pass in certain specified subjects during a given period.

In Rudiments of Music, Higher and Elementary Certificates will be given; in Harmony, Higher, Intermediate, and Elementary Certificates.

A fee of 2*s.* 6*d.* will be required by the Society from each Candidate in each subject in the Advanced and Intermediate Stages, and in the Elementary Stage a fee of 2*s.* for one subject, and 1*s.* for each additional subject taken up by the same candidate. The fees for Harmony and Rudiments of Music are the same as for Stages II. and III.

Medals and prizes are offered in each subject in Stages II. and III.

Examinations are also held in the Practice of Music, and Viva Voce Examinations in French, German, Spanish, Portuguese, and Italian.

THE RAJPUTS IN THE HISTORY OF HINDUSTAN.

By Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D.

Part II.

The English in India.

In the reign of Jehanghir, 1605–27, the ever-smouldering disaffection of the Rajputs was, after a reverse suffered by the imperial troops in 1610, appeased for a time, on terms most advantageous to the Rana of Mewar, Amara II., the grandson of Udai Sing. Shah Jehan, the third son of Jehanghir, owed his succession to the throne of Delhi, 1628–58, to the support given him by the Rajputs, who in his reign were equally powerful in the court, and the camp of the Great Mo(n)gol. The year of his succession was also the year of the birth of Sivaji, the man of men destined to reanimate the Mahrattas with that Aryan passion for personal freedom and pride of race, which, under unparalleled adversities, had sustained the Rajputs through 800 years of uncompromising hostility to the rule of the Arabian, Afghan, and Mo(n)gol Mahometans. The auspices seemed favourable to the future of India—India of the Hindus; but the Mahrattas were new to the responsibilities of power; while the Rajputs in the course of their prolonged struggle for very existence with the Mahometans, had lost something of the foresight and sagacity of their once magnanimous statesmanship; and instead of uniting in a common policy toward the Mo(n)gol Empire, these inherently patriotic Hindu nationalities entered on a fratricidal contest for predominance at Delhi; with consequences that would have brought universal ruin on India, but for the tardy and reluctant, but at last definite interposition of the English in their internecine warfarings. Aurungzib,* "the

* Zib, "Ornament," occurs also in the name of his daughter, Zibanisa, "the Ornament of her Sex," the poetess

Hosted by Google

Ornament of the Throne," otherwise known as Alumgir, "the Conqueror of the Universe," the perfidious, intolerant, fanatical, and cruel, fourth son of Shah Jehan, secured the succession to the throne by a series of the blackest and most barbarous of murders. Both Jeswunt Rao of Jodhpur and Jai Sing of Udaipur had assisted him against Sivaji; but his reimposition of the poll tax alienated the loyalty of the Rajput Princes; and his vindictive treatment of the widow and children of Jeswunt Sing drove them again into open revolt; and they were conciliated only by the remission of the tyrannous and obnoxious tax.

Under Bahadur Shah, otherwise Shah Alam I., 1707–12, the grandson of Aurungzib, the Sikhs and Mahrattas gave great trouble at Delhi; and on an alliance being formed between Rana Amira II. of Udaipur, Sivaji Jai Sing of Jaipur, and Ajit Sing [son of Jeswunt Sing of Jodhpur], virtual independence was granted to Rajputana. For the support rendered at this crisis, and in the previous rebellion against the poll tax, by Jaipur and Jodhpur to Udaipur, they had restored to their Houses the privilege of marriage with Udaipur. Unfortunately, the concession revived the antipathies excited against the former families for having given their daughters in marriage to Akbar and Humayun, and greatly aggravated the rivalries among the Rajput Princes for marriage with the pure-blooded princesses of Udaipur; the tragical issue of one of these romantic feuds directly leading at length to the establishment in 1817–18 of the British protectorate of Rajputana.

The eighth Mo(n)gol, 1712, a son of Shah Alam I., the ninth, 1712–19, and tenth and eleventh, 1719–20, all grandsons of Shah Alam I., are empty names; but the ninth, Farukshah, may be named because of his marriage, in 1713, with a daughter of Ajit Sing of Jodhpur. Muhammad Shah, the twelfth Mo(n)gol Emperor, 1720–48, was entirely in the hands of the Mahrattas, to whom he granted the *chouth*, or "one-fourth" of the revenues of the Dakkan. The Mahrattas being called in by Jagat Sing II. of Udaipur to assist him in asserting the claims of his nephew to the vacant *gadi* of Jaipur, also received for this service the *chauth* of Mewar, and the session of the District of Rampur. But the outstanding event of Muhammad Shah's reign was the invasion of India by Nadir Shah, 1738–39, with its climax in the bloody massacres of Delhi, and the symbolical abduction of "the Peacock Throne" of Shah Jehan. In the last year of his reign India was again invaded, this time by the terrible Ahmed Shah Abdalli, one of the lieutenants of Nadir Shah in 1738–39. He was met and repulsed by Muhammad Shah's son, and successor, Ahmed Shah, 1748–54. But "the Abdalli" was permitted to retain possession of the Panjab [Lahor and Multan] as a solatium for a check recognised as full of menace for the future of the Mo(n)gol Empire. Under Alamghir II., the fourteenth Emperor, 1754–59, a brother of Muhammad Shah, the dreaded Abdalli once more crossed the Indus [1756, the year of "the Black Hole"], and having seated his infant son in the government of the Panjab, marched on Delhi, and entered the city on September 11th, 1757 [the year of Plassey]. But pestilence breaking out in his army, he at once, with his prolonged lumbering trains of high-packed *loot*, marched back to Kabul.

The nominal reign of Alamghir's son, Shah Alam II., was from 1761 to 1806. As soon as "the Abdalli" was out of sight, the wirepullers at Delhi incited the Mahrattas to plunder the Panjab, and this most ill-advised, if brilliant, adventure again brought "the Abdalli" down upon Delhi. After many marchings and countermarchings, the Mahrattas were at the last driven to bay, and entrenched themselves at Panipat, there to await the onset of the Abdalli. His force was less numerous than theirs; while careful, therefore, to watch them on every side, he resolved to wait until they were starving before he destroyed them. He had not to wait long, for on the eve of January 6th (our "Twelfth Day"), 1761, Sivadasa Rao sent round the word: "The cup is full to the brimming, and we must drink it down to the dregs"; and at dawn the following day, hounded on by hunger, the whole army moved out to the attack, 65,000 horse, 15,000 foot, 200 cannon, and 200,000 Pindharis, the Chinchuses of their date. The Sindhia was on the right, the Holkar, with the Rajput auxiliaries, in the centre, and the Mahrattas from Sivaji's *svai-raj* ("Own-Kingdom," compare *svaideshi*, "Own-country") on the left. The latter, "the dalesmen" (*mavalis*) of the Western Ghats, between Poona and Sattara, drove back "the Abdalli's" right, and the Rajputs and Jats drove back his centre, and the fortune of the day would have been with the Hindu army, but that the Holkar at

Hosted by Google

this moment treacherously abandoned the field, and was incontinently followed by the Rajputs. "The Fourth Battle of Panipat" then became the Armageddon of the Mahrattas.

The fight fought, and Delhi well looted, the Abdalli returned to Kabul, where he died, having no bonds in his death, in 1773.

At Delhi itself everything was left in confusion worse confounded than before; sometimes the Mahrattas securing possession of the person of the puppet Emperor, and sometimes the Mahometans, each in turn wielding his still controlling sceptre as the madder "Lords of Misrule."

Rajputana suffered terribly during the chaos. In Mewar the Rana Jagat Sing, 1733–51, had, as already said, surrendered Rampura, and agreed to pay half *chouth* to the Mahrattas. In the reigns of his successors, Raj Sing, 1754–61, and Arsi Sing, 1761–71, the State was constantly overrun by roving bands of these freebooters; and the Rana, Amira II., 1771–7, was compelled to yield up several districts to the Scindhia and the Holkar of the period. But it was in the early part of Bhim Sing's long reign, 1777–1828, that Mewar suffered most from the senseless and ruinous raids of these marauding Mahrattas. Jaipur and Jodhpur were treated in the like manner, but the energetic Jaipur Prince, Pratab Sing, 1769–1803, in alliance with the Jodhpur Prince, Vijaya Sing, 1752–93, succeeded in inflicting condign chastisement on them at the battle of Tonga, 1787; when Vijaya Sing obtained possession of Ajmir, after it had been held continuously from 1756 by the Mahrattas.

It was inevitable that England would be drawn into the vortex; but the pressure of the Mahrattas was first felt by the Honourable East India Company chiefly in Southern India. The complications of the position were perplexing, but Warren Hastings * was now at the head of affairs [1772, 1774–85], and at the right moment ordered Colonel Leslie to lead a force from Calcutta, diagonally across the breadth of the peninsula, upon Surat; and on Leslie's showing himself a little dilatory in his preparations for the adventure, forthwith replaced him in the command by Colonel Thomas Goddard,* who, starting off from Calcutta in October, 1778, reached Surat on February 6th, 1779. This memorable feat of combined political insight, sagacity, courage, and military skill and vigour, was vehemently denounced in England as "a frantic exploit." The reply is, that but for such heroical frenzies the English would never have been Lords Paramount of India: and the triumphant result of "Goddard's March" was the Treaty of Salbai, 1782, regulating the future relations of England with the Mahrattas, and the Nizam, and "Tipu Sahib." The prestige of the Mahrattas having been lowered by Goddard's splendid achievement, and further injured in Hindustan by the victory of the Rajputs at Tonga, they lost for a time their influence at Delhi; and Shah Alam II. passed into the hands of the Mahometan faction of the Mo(n)gol Court. Suspecting that he had amassed great treasure, the Rohilla,† Golam Kadir, to induce him to reveal the place of its concealment, put his sons [the second was Akbar II., the sixteenth Mo(n)gol Emperor, 1806–37], and grandsons [the son of Akbar II. was M. Bahadur, the seventeenth and last Mo(n)gol Emperor, 1837–57], to piteous tortures before the presence of the unhappy monarch; and this failing of its fell purpose the Rohilla Chieftain, in his fiendish rage, snatching

* See Sir John Strachey's "Hastings and the Rohilla War"; G. W. Forrest's "Selections from the Records of the Foreign Department of the Government of India," 1772–85; and Sir Charles Lawson in "The Journal of Indian Art and Industry," 1892, on his pilgrimage to the grave of Warren Hastings at Daylesford. Sir Charles Lawson's monograph is of particular interest and value, proving as it does, and all the more impressively because quite unintentionally, that the success of Warren Hastings as a public servant was based on his solid English worthiness in every relation of private life. He was the subject of the most cruel calumnies by the "little Englanders" of his day, and his memory has for nearly a century been obscured by their scandalous misrepresentations; but men like Warren Hastings always have God on their side, Who, if patient, is unerring in His law, clearly and strongly in the end discriminating between right and wrong. While, looking through Sir Charles Lawson's illustrations, one cannot help feeling that after all it is some reparation for the wrongs a man may suffer in life, to lie in death in so unpretentious and tranquil an English grave as that wherein Warren Hastings sleeps at Daylesford, the very place of his birth, and instinct with spirit of the antique benediction: "Peace be here" [Ευφημια 'στω]. In the darkest hours a statesman can know—when the beneficent results of the labours of years are suddenly exposed to destruction by party politicians, with their wild mad whirlwind of winged words, wielding the ignorant, wayward masses to their will, and he is assailed on all sides by the parasites of these demagogues, base-bred, foul-mouthed, mean fellows, Thersites-like, apt in all the vile arts of contumely and detraction,—in such hours of personal affront and insult, and evilest national portent, the tardy but complete vindication the private and public character of Warren Hastings has at length received, should reanimate faith and hope, and the sweet serenity of his sequestered grave breathe balm.

* Afterward Commander-in-Chief of the Bombay Army. Falling sick, and "invalided home," he died in sight of the Land's End, July 7th, 1783.

† The Rohillas [from *rohu*, "a mountain"] were Afghans [the Assakani—from Sanskrit *asvaka*, "horseman"—of the Greeks] who settled in and gave their name—Rohilkhand—to the country between the Jamna and the Ganges, about Bareilly, Moradabad and Bijnour up to the Tarai. They cleared these districts of their Hindu inhabitants; and their later encroachments on Oude led to the Nawab Vizier of that country seeking the protection of the English against them; which was at once given by Warren Hastings, 1781.

Hosted by Google

the dagger from Shah Alam's girdle, gouged out both his eyes with it, casting them one after the other to the ground. The Mahrattas now regained their hold of the poor blind Emperor; and, using their opportunity to cause trouble once more in Southern India, brought on another conflict with us, 1803, "the Second Mahratta War," so called. After Wellington's victory at Assaye, September 23rd, 1803, it was most satisfactorily concluded by "the Treaty of Deogaom," of December 17th, 1803, with the Bhonsla [Mahratta ruler of the Sivaji family] of Berar, and "the Treaty of Argengaom," of December 30th, 1803, with the Sindhia; a marvellous year's work, due chiefly to the energy of the Marquis of Wellesley, as Governor-General, 1791–1805. Subsidiary treaties of protection were made with Jaipur, Jodhpur, and others of the Rajput States. These treaties were condemned "at Home" as committing England to the virtual "Protectorate of India"; and this weak, evasive demeanour of ours [that is of the Parliamentary "Opposition" of the day], before an obvious duty, disheartening the Rajputs, and encouraging the Holkar,—who, owing to the vacillations of policy caused by political cowardice of "the Home Government," had all along been left at large,—he at once fell upon Rajputana, and thus brought on "the Third Mahratta War," April, 1804, to December, 1805.

Although the Holkar caused some trouble, Lord Lake cut him up severely at Fatehghar. But the simultaneous delay in the siege of the Jat fortress of Bhurtpur emboldening the Sindhia to join the Holkar, a preposterous panic seized on the authorities at Home, who, in July, 1805, sent out Lord Cornwallis to Calcutta with express instructions to restore peace at any price. A separate "peace," in which there was no peace, was at once made with the Sindhia and the Holkar; and, although they both were absolutely in our power, the shameful and shameless price we paid for it was the sacrifice of our faithful allies in Rajputana to the unleashed vengeance of their hereditary foes. Mewar, still under Bhim Sing, was scoured from end to end by the Sindhia and Holkar, and the notorious Afghan adventurer, Amir Khan, the ancestor of the Nawabs of Tonk. The cities were destroyed, the forests burnt down, the fields laid waste, and the people driven with feline ferocity up into the unassailable and safe fastnesses of the Aravali and Satpura Hills, and Vindhya Mountains. Jaipur, under Jajat Sing II., 1803–18, was similarly devastated and desolated; and Marwar, where Man Sing's first act on the *gadi*, 1803, was to assent to the repudiation by ourselves of the treaty of protection we had solemnly entered into with his predecessor, "in articulo mortis," was left by us to the same lamentable fate. But the most abject and basest betrayal of all was of the little Rajput State of Bundi. When the British, under Colonel Monson, were retreating before Holkar, July 8th to August 31st, 1804, they at length reached Bundi, where Umed Sing, disregarding the reprisals of the Holkar, gave them a most cordial reception, rendered them every possible assistance, and conducted them safely through his kingdom, and out of all pressing danger; thus fulfilling to the letter, and in the frankest manner, the obligations we had enforced on him in 1803. Yet, and in spite of Lord Lake's protestations, we left him completely disclosured to the ruthless vindictiveness of the Holkar; for the Government in London had given their panic-stricken orders, and the abdominous and slouchy General who had surrendered New York, and made the inconclusive Treaty of 1702 with "Tipu Sahib," good slogging fighter though he was, had not the stuff in him to turn, in reply, upon the contemptible authorities in England with an accomplished fact overmastering all remonstrance or reproof.

Further serious aggravations of the troubles created by the policy initiated through Lord Cornwallis, were stayed by his transparently providential death; and when the Earl of Minto went out as Governor-General, 1807–13, the fatal consequences of our dastardly truckling to the Mahrattas were so obvious, that the exercise of the greatest discretion was required on the part of the Government of India, if order and peace were to be maintained in the country.

Then occurred the strange, sinister quarrel between Jaipur and Jodhpur for the hand of Krishna Kumari Bai, the younger daughter of the twice aforesaid Rana Bhim Sing, 1777–1828, of Udaipur. She had been betrothed to Bhim Sing of Jodhpur, 1793–1803; and on his death was claimed by his successor, Man Sing, on the specious plea that her betrothal was to the throne of Jodhpur, and not to the person in passing occupation of it. Her father, however, had already betrothed her to Jagat Sing, the effeminate and debauched Prince of Jaipur. The lovely Kumari Bai, born in 1792, was barely twelve years of age at this time; and for the next seven years Rajputana was convulsed by the rivalry of Jaipur and Jodhpur for her

innocent little hand. Nearly every Prince and Chief in Rajputana took part in the direful quarrel;—a revival in the nineteenth century A.D. of the great mythical war in the fourteenth century B.C. of the *Mahabharata;* and on its very scene. In a fatal moment both sides sought the support of the infamous Amir Khan, and his brutal banditti of renegade Mahrattas and Pindharis; who accorded it, now to the one side and now to the other, as they outbid each other for his mercenary and merciless sword. In his extremity the Rana of Udaipur besought the intervention of the English. Under the influence of the cruel orders from Home, this was refused; and, driven to despair, the miserable father yielded to the demand of the scoundrel Amir Khan to have his daughter murdered. She was now eighteen, and Greek in the grace and sweetness of her perfected loveliness; and, obedient to a fate that would, as was hoped, bring her royal House and renowned country peace — attired as a royal bride—taking the poisoned [opiate] *Kasamba* bowl, timidly proffered to her by her distracted father, and crying out gallantly :—" This is the bridegroom foredoomed for me ! "—she drank it to the last drop, falling down on the floor, in a deadly swoon, at the feet of her weeping handmaids. The heart-breaking tragedy filled India, and filled England, with horror, anguish, and remorse; and served more to convince the conscience of the people of England of the iniquity of our pusillanimous perfidy toward Rajputana, after "the Second Mahratta War," than even the representations of Lord Minto on its improvidence and folly.

It fell to the Marquis of Hastings, as seventh Governor-General, to carry out the virile policy recommended by Lord Minto; and, after settling scores with Nipal, he carried through his short and thoroughly effective campaigns of the year, October, 1817, to February 10th, 1818. They were signalised by the victories of Kirki, Nagpur, Mehedpur, Korigaum, and Ashte, involving the virtual extermination of the Pindharis; and were felicitously terminated by "the Treaty of Mandeshwar," in Rajputana, whereby a final accommodation was come to with the Mahratta States of the Dakkan, and the British Protectorate over Rajputana was reaffirmed and permanently constituted. The Holkar had to give up the whole of his ill-gotten territories in Rajputana; and the State of Bundi was liberally compensated for its disinterested loyalty to the British Raj.

"And thus in happy days, and rest, and peace," "the Fourth Mahratta War" was brought to its beneficent end.

Memories.

The fort of Asirghar, indeed, was not taken until April 9th, 1819. It crowns an isolated hill of the Satpura ["Seven-towns"] range, south of Mhow and Indor, both away on the other side of the river. I lived in the fort some two years between 1832 and 1839; and I believe I can correctly recall every prominent feature of the fortress, and of the rock on which it stands. I certainly could draw a good ground-plan of its platform, and a recognisable silhouette of its profile; and I well recollect the awe and execration with which to that day the people about me spoke of the Pindharis in the last Mahratta war. The large beaten brass *gindi* ["hollowed"], in which I tubbed, and which I took with me to England in 1839, had been an unconsidered portion of the prize booty recaptured from the Pindharis some fifteen years previously. And on every one of the six occasions on which I crossed the Nerbudda, going and returning from Mhow and Indor, or from excursions into Rajputana, there was some murderous scrimmage afoot along the rough countryside overhanging the right bank of the river; and every day *Bhils* were to be seen from afar following the jungle tracks through Khandish, when I was visiting my uncle at Dhulia; and arrows were discharged at the palanquin, or the pony, wherever I happened to be borne. This condition of things, between only seventy and eighty years ago, is now entirely forgotten, if it was ever realised by the sleek dwellers of the populous maritime cities that have grown up in India under the ægis of the British Raj—Calcutta and Madras, and Bombay and Karachi. But they remain living memories for Khandish, Malwa, Bhopal, and Rajputana; and in all the domestic histories of the reigning Rajput families, after the sickening record of the untoward calamities of the fifty-seven years, from 1761 to 1818, there is a sudden change to the joyous and frankly grateful acknowledgment made of the improvement in the material and moral condition of the country and in the position of the sovereign Princes, under the terms of the Treaty of Mandeshwar; and in every instance these histories associate the redemption of Rajputana—as of a brand plucked out of the burning—with the ever-revered name of Colonel James Tod.

Reflections.

This is the round, unvarnished recital, running through twenty centuries, from Alexander the

Hosted by Google

Great to Muhammad ibn Kasim, and onward to Karim Khan, of the unflinching and inflexible antagonism of the high-souled Rajputs against every intruder into India, and every hateful persecutor of "the Twice-born" Hindus; a hostility inspired to the last, as from the first, by the unquenchable love of individual freedom and the unswerving, self-sustained fortitude, denotative of every true-blooded Aryan race. In all the unrivalled record of their interminable warfarings, whatever the emergency of their merciless fate, their spirit was never broken, and whatever the storm and stress of unequal battle, their rent flag was never lowered. When it could no longer be upheld, they raised the dread signal of the rallying *johur;* and shoulder to shoulder, and back to back, fought their feud out to the well and righteously purposed end of every good fight between gentlemen of "fire i' the blood."

The practical reflections suggested by the trumpet-tongued chronicle, and pressed by it as well upon us Englishmen as upon Rajputs, are:—What causes have conduced to the vitality of the Rajput passion for personal virility? and, What lessons have the results of them, as read in their history, for themselves, and, in especial, for ourselves?—not as an imperial people, for that wider scope of the question lies beyond my province here, but as individual men, living the round of our daily lives among other men. The less invidious course will be to let the reply to the first interrogation be the reply also to the second; and it is this:—The predetermining and preponderating influences in the development of the strong historical personality of the Rajputs have been the superiority of race they as Aryas share with the English and other Germans in Europe and North America; and with the French and other Latins, and the Greeks of Southern Europe; and the Russians, and the Persians; and the proper pride fostered in every man of them by the self-consciousness of their ethnical superiority; and the instinctive exclusiveness, engendered by this pride, with which they have, by vigorously avoiding mixed marriages, sought to sustain the pristine purity of their pan-Aryan strain. The distinguishing note of this superiority is virility, as shown in every worthy and beseeming quality implied thereby — temperance, endurance, patience, courage, fortitude, equity, and, above all these, because the sum of all these, magnanimity; and again, in all these natural virtues, educated to their perfected expression in the character of chivalrous men. Of such are "the brave in the dark," the darkness of forgotten history, "the heroes before Agamemnon"; and again, the innumerable English youths, beardless striplings, "steeped in honour and in discipline," who yearly yield up their lives in our army and navy, a last sacrifice to patriotism, "unwept, unhonoured, and unsung," because there is no Homer to immortalise their deeds.* Their daring is its own reward, and their one desire to find in the "enemy" they needs must meet an equal daring to their own. In Fletcher's "Bouduca," the prayer of Caratach ["Caractacus"] to the British War-God, Andate,† is:—

"Give us this day good hearts, good enemies,
Good blows o' both sides, wounds that fear, or flight,
Can claim no share in:—
Let Rome put on her best strength, and thy Britain,
This little Britain—but as great in fortune,—
Meet her as strong as she, as proud and daring."

This is the prayer of every British soldier's heart when marching into "the Field of Slaughter," and this was the prayer from the heart of every Rajput Prince when solemnly entering on a campaign against Delhi, Gwalior, or Indor, addressed to their supreme War-God, the Lord Siva, in his most eldritch sanctuary of Vindhyan Ekalinga.

This virility, the essential and fundamental element of all natural, manly virtue, has been perpetuated from father to son, through at least seventy generations, among the Rajputs, by their ancient system of domestic education. They have never confounded instruction with education, for they have never confounded knowledge with character, but have ever recognised that manual dexterities and mental acquirements, the inherent powers of the intellect itself, are vain things, unless behind them is the inspiring, guiding, controlling, co-operative, and omnificent force of a fearless, resolute, just, and benignant character, matured in the warriors of Rajputana by two thousand years of the stubbornest oppugnancy to the most heaviest malignancies of Fate; and refined

* "Qui procul hinc"—the legend's writ—
The Frontier grave is far away!
Qui ante diem periit,—
Sed Miles, sed PRO PATRIA."

† Andate, Andraste, or Andras, was a "goddess," and in Fletcher's "Bouduca" [Boudica, "Boadicea"] the word "god" is applied to her simply as the masculine of honour. The speech Fletcher puts into the mouth of "Caratach" [Caradoc, "Caractacus," ? Caird] should be compared with one of the Latin ballads of the period of the decline of the Roman Empire, sung by the Legionaries after a victory:—

"Mille, mille, decollavimus,
Unus homo mille decollavimus.
Mille vivat qui mille occidit.
Tantum vini habet nemo
Quantum fundit sanguinis."

Hosted by Google

and elevated to a national, or rather, an ethnical ideal, by the obligation to study the history of that per-enduring argument of shed blood, imposed as a religious duty on every young Rajput of any pride in his generous race and ennobling lineage; this history being taught him, not in its dead letter of dates and statistical tables, but in its living and moving spirit as caught and handed down from man to man by the glowing genius of their tribal poet Chand Bardai. The *Mahabharata*, the *Ramayana*, and the *Prithviraj Chauhan Rasha* are the choice historical library of every Rajput gentleman; and this, simply, is why, in spite of all the calculators, the economists, and the sophisters with whom we have overflowed India, and who have for ever extinguished the epic life of Europe, "the Age of Chivalry," has not passed away in India. These poems have the same virtue in forming the historical personality of Rajputs as that exercised by the "Iliad" and "Odyssey," the plays of Shakespeare and the Bible—books that "show, contain, and nourish all the world,"—in moulding the national character of the English, as we recognise it at the very zenith of its typical and specific greatness, in the Eighteenth Century. Germany, England, and the United States of America owe everything they are, and have, to their vernacular versions of the Bible; the bed-rock of their national greatness and glory, and the sure staple, proof, and bulwark of their defence in the warfare for righteousness against "a whole world in arms"; and so long as they remain true to Luther's German rescript of the Bible, and we Anglo-Saxons to our "Authorised Version"—for both America and England that other "well of English undefiled"—it may well be asked of the three,—"Quis separabit"?

To steep and imbue the souls of men, and from childhood, in these books is indeed what alone can quicken the dead clay of mere clerical and technical proficiency into operative life, and unquestioned magistery; and of all professional experts, this baptism of the true Promethean fire, is the imperative pre-requisite of the warrior who would be a leader of warriors, of the type of—

"Henry the fift, that man made out of Fire,"

as he is finely phrased by Drayton; and, coming to our own generation, those other right heroical and illustrious Agnikulas, the Viscount Wolseley, the Earl Roberts, and the Viscount Kitchener of Khartoum. In the *Rig-Veda*, the Poet and the Warrior are one; both are Agnikulas. The hero fires the Poet, and the Poet in return rekindles the fecund flame in other heroes.* The one has no life without the other; only the poet is ever the predominant partner in their common fame. This is tersely told in Sir John Vaughan's lines [1631] "Upon the Battaile of Agincourt"—

"What *Povver* is a Poet; that can add
A life to Kings, more glorious than they had.
For what of Henry is unsung by thee,
Henry doth want of his Eternity."

To say nothing of "the Seven Arts" ["the Trivium" and Quadrivium," answering to "the Seven Planets," the three outer and four inner], which in themselves are poetry,—in the very mechanical and industrial arts the heroic spirit, which is the poetic spirit, is equally necessary, if they are to be elaborated to their paradigmal ideals. The scattered *Silpa-darpana*, "Mirrors of Art," of the Hindus, are all, so far as I have known them, written in metre, and many who have never been in India will have observed at the Earl's Court Exhibition how the Hindu weavers of carpets and other artistic fabrics, chaunted in their archaic patternings to the time of their flying shuttles, with the unfailing ascriptive refrain—*Ram! Ram!*—"Glory to God in the Highest." The whole worship of the Hindus is hymned. Anthems, Antiphons, Grayles, Introits, Proses and Sequences, all are there. And, therefore, it happens that the still living Industrial Arts of India, and the still living Chivalry of Rajputana, and the still living Religion of the Hindus—of the Mahrattas and Tamils in special—are the three only "points" on which there is any possibility of rallying and regenerating the national life of Aryan India—India of the Hindus.

"Verba Novissima."

I began by acknowledging my obligations in the preparation of this paper to James Tod and

* Simon Ockley, in his wonderful "History of the Saracens," relates how at the battle of Aignadin, July 13th, 633 A.D., wherein the Emperor Heraclius I. was defeated by Kalid, the celebrated general of the Caliphs Abubekr and Omar, the patriotic Arabian women danced behind the rear ranks of the Saracen army, as it advanced to meet the Greeks, singing: "Fight on, fight on, and we kiss you, and embrace you! Turn not back, turn not back, or we scorn and spurn you!" On the first charge of the Imperial troops the Saracens did turn back, and would have fled, but that the women rallied them with their taunts and gibes; when, refacing the Greeks, Kalid gained the victory over Heraclius. Of this character must have been the Saltatiunculæ, and Ballistea, or ballads, sung to dancing, and in the tetrametric trochaic step of the war dance of the Roman armies; and the form of these ballads thus quite naturally became that of the earliest hymns of the Christian Church Militant. In the advancing procession of the Muharram, as witnessed in Bombay, the dancing "beat" of the "Tiger-men," and other mummers, is exactly timed to the catalectic tetrametric trochaic ballad metre.

Miss Gabrielle Festing.* She has given us all the more notable episodes of the tragic history of Rajasthan in a form that renders them generally accessible to English readers. In their strange atmosphere and outland circumstance they are fairy tales, but of the faery of real life, the direction and control of which, by a strange eventful Providence, has passed into English hands. But these stories will be profitable to us not only in familiarising us with something of the typical history and character of a magnanimous and mighty Indian people, whose future we may make or mar. They will be gainful also in stimulating in their English readers those virilities that are as instinctive in themselves as in the Rajputs. The human heart is ever animated and encouraged by the recital of tales of heroism, and Miss Gabrielle Festing's stories, "From the Land of Princes," cannot but lead those who read them to mark, learn and consider, with many close and intimate self-searchings, the clear, fixed, and unflinching view taken of life and of its inexorable necessities and stern responsibilities by the traditional Rajput gentleman; and to receive into their own bosoms some radiation from the fire and splendour of his steadfast and matchless valours. Where duty calls, the Rajput ideal gentleman knows no whimpering scruples, no debauched and impotent sentimentalities:—

"Work of his hand
He nor commends nor grieves.
Pleads for itself the Fact—
As unrelenting Nature leaves
Her every Act."

The book is sure to do good among the Rajputs also, if only by the gratification it has given them as a proof of the popular interest in their sacro-sanct country of "The Seven States" felt by us in this England of our own:—

"This royal throne of kings, this sceptred isle,
This earth of majesty, this seal of Mars,
This other Eden.
* * * * * *
This blessed spot, this Earth, this realm, this
England."

It will revive their pride in their own country and themselves, and will, I would fain hope and anticipate, lead at last to the rebuilding, in pure white marble, of Chitor, on the old ground-plan, still easily to be traced amid the ruins of the city. This would be a national Rajput achievement of the most auspicious political significance.

Of not less felicitous augury would be the dedication, by the Government of India, of the whole Kurukshetra, or "Kuru's-field," the battlefield of Staneshwara, and field of all "the Battles of Panipat," to the perpetual service of the public, as an inviolable sylvan sanctuary, on the scale and after the manner of "the National Yellowstone Park" in America; and as an Indian national park worthy at once of the imperial Delhi of the past and of the future.

Furthermore, Miss Festing's book should prepare the way for a new edition of Tod's great work, edited with the same conscientious reverence for the original text of "The Annals and Antiquities of Rajasthan," as has been shown by that eminent Orientalist, Mr. William Crooke, in his edition of Yule's "Hobson-Jobson," and by Henri Cordier in his edition of Yule's "Book of Ser Marco Polo." A reproduction of Tod's "Rajasthan," in the same loyal and worthy spirit and form, would have an immense effect in rearousing in the Rajputs a beneficent sense of their commanding place alike in the past and the future political life of India. What great publishers [it ought to be the India Office] will commission, say, Sir William Lee-Warner and Mr. W. Crooke to prepare such an edition for them, brought down to the date of the Delhi Durbar of last December? At the parting of ways whereat we stand to-day in India, its publication would do more than the "rattling" of arrows [by party publicists and politicians], the looking into the livers of sacrificial victims [Anglo-Indians], and the mixing of oil and vinegar [in the Indian Viceroys and the Indian Secretary of State's Councils], to determine the divination, whether to keep forward by the right, wreathed with olives and laurel or roses, or turn to the left, bearing the unsheathed sword to resistless slaughters. The years 1918 and 1957, in the prevision of those who know, not only the history of Hindustan, but something of the hiero-psychical temperament of Hindus, are full of the farthest-reaching fates of the future of "Sri Bharata," [the "weighty" earth whereof, and water, air and sunshine, I also took truest nativity, and pulsated into this mortal, human life some fourscore years since]; emphasised as these are by the passing, now in actual progression, of the sanctity of the Ganges to the Nerbudda:—a predication that is a simple

* An acknowledgment of my indebtedness is due also to Shri Cheda Sing Varma's "Kshatriyas and would-be Kshatriyas," Allahabad, 1894; and to Shri Purshotam Vishram Mawje's, "Shivaji's Swarajya," read before the Bombay Branch of the Royal Asiatic Society, December 19th, 1903.

induction from an overmastering multitude of ethnographical, physiological, psychological, and historical facts; unbiased by any whisper of the "mystical lore" that comes to all men with "the sunset of life."

THE AGRICULTURAL ORGANISATION OF FRENCH EQUATORIAL AFRICA.*

French Equatorial Africa, more commonly denominated French Congo, has recently attracted a good deal of attention on account of the political treaty which has modified its area, but very few people know the real importance of its internal organisation. Therefore the study of the subject in the number of the *Bulletin of Economic and Social Intelligence* of the International Institute of Agriculture for June, 1912, will not fail to be remarked.

A first glance at the country permits of its division into three zones: a wooded coast region, the principal wealth of which consists in rubber; an inner district of steppes suitable for livestock improvement and cultivation; and finally, a desert region. About two-thirds of the part ceded to Germany is land producing rubber, the rest consists of land suitable for livestock improvement and cultivation; no portion is desert.

These regions cannot be exploited without great difficulty. There is so great a want of resources in the first-mentioned zone, that even at Brazzaville itself the market does not supply sufficient food for the population. More than in any other colony, the Europeans have to resort to preserved and other imported food. The interior produces more, but it again suffers from another drawback: its extreme distance from the coast. Finally, over an area equal to that of France, the land is burdened by the heavy mortgages of the monopolist concessionary companies. The study in the *Bulletin of Economic and Social Intelligence* deals at length with the position of these companies, but enables us to foresee the end of the concessionary *régime*. The governor of the colony himself has recently said:—

"Of eighty-one millions of immobilised hectares, nine have been restored to the Crown and to free trade, twenty-two others will be so restored within a term of ten years. This will lead more certainly towards the complete liberation of the soil, as such a movement, once begun, cannot be arrested."

The problem of native reserves is of greater delicacy, and it has been necessary to cancel the provisions of the Leopold Code, which reduced them to the area now utilised by the blacks. In fact the cultivation in use among the blacks is extensive. They burn the bush, sow and reap in the part fertilised by the ash, letting the bush then grow again and transferring their operations elsewhere. Their use is, further, to cut and gather wood in the forests or burnt over a certain area. This entire group of habits must be respected, but this will not hinder the teaching of better methods.

Another question of the day is that of labour contracts, which is the more important, as, labour being insufficient in Equatorial Africa, all the European colonies contend for it. Thence the tendency of the colonists to try to obtain contract labour, which may sometimes mean that of mere savages; while in addition to this we have the fact that labourers are often recruited by exporting companies which address circulars to the employers of labour. On the application of the colonists the labourers are sent to them on payment of a sum in advance. This is not all the profit of the "exporter"; in fact, at the end of a year, the term of the engagement, the natives are sent back to the place where they were recruited, and the payment of two-thirds of the wages promised them is made in goods by the recruiting company. One native, it is said, would receive for a year's work a supply of earthenware plates and bowls; another a supply of stuff, the greater part consisting of eyeglass cords.

It will be understood that in face of such a state of things the public authorities have been anxious to regulate the labour contract. After other measures, the imperfection of which has been recognised, a decree of April 7th, 1911, prescribes, among other things, a compulsory medical examination, with a view to prevent the engagement of too weak or too young natives, and the payment of the whole wage in money. The provisions will also be observed that relate to the return of the labourers to their homes, the attention to be given to them in their employment when ill, and the compensation they may claim for accidents in their work. The blacks of French Equatorial Africa benefit by a real system of insurance without contributions on their part, which the future will scarcely have to do more than complete.

* Summarised from the *Bulletin of Economic and Social Intelligence* of the International Institute of Agriculture, Rome. Year III., No. 6. June, 1912.

BELGIAN LACE-MAKING.

"La Dentelle Belge," by Dr. Pierre Verhaegen, provincial councillor and political and social economist, is an important work produced under the auspices of the Belgian Ministry of Industry and Public Works. It consists of nearly 300 pages of letterpress interspersed with eighty-five attractive and large illustrations, not only of typical specimens of Belgian lace—needlepoint and bobbin made —many of elaborate design, but also of Belgian lace-makers at work in their homes, at their doors in streets and country lanes, in almshouses, and in convent work-rooms.

Chapter I. treats of the past history of the industry, and will probably be found by the general reader to be the more interesting. In it Dr.

Verhaegen discusses various documents, patterns, books, and the like already known to historiographers of lace. Following the majority of them, he argues in favour of contemporaneous development of the artistic side of the art-craft in Flanders and Venice; but he considers it impossible to assign precise dates to the oldest extant specimens of lace—a task, however, which is really not of such insurmountable difficulty if one takes a broad view of the evolution, so to speak, of different methods of working threads into a pattern. For instance, the method of twisting and plaiting many threads together to form a pattern or recurrent ornamentation is common to all bobbin (pillow) lace-making, and is conclusively indicated in Assyrian bas-reliefs of potentates wearing rich costumes variously fringed and tasselled; and although it is a far cry from the Mesopotamian districts of 700 B.C. to the lagoons of Venice or the plains of Flanders in the sixteenth century A.D., there is, of course, distinct technical relationship between the make of Assyrian fringes and that of Venetian *merletti a piombini* and the Flemish *Dentelles aux fuseaux*. Again, looping a continuous thread to form an ornamental device either as an insertion into or an enrichment of linen, or independently of linen—such as Italian *reticella*—or *punti in Aria*, is a method of work the close parallel to which one finds in variegated nets made by Egypto-Romans and Copts soon after the opening of the Christian era: and looping a thread with a needle is the essential process in constructing a needlepoint lace.

The intricate ornament which can be done by twisting, plaiting, or twisting and looping fine threads together is due in the main to the influences exerted on the workpeople by peculiar circumstances of taste, the fluctuations of which can be associated with various periods. Now the conditions of culture, luxury, and intercourse were so nearly alike in Italy and Flanders in the sixteenth century, which is the time when dainty and primitive lace trimmings were first made for costumes, that both countries might have devised almost identical patterns for an insertion or a purled edging. The styles and varieties of lace then succeed one another in chronological order, some becoming identifiable with lace-making districts and thus giving rise to the adoption of local names for them. Apart from laces, pure and simple, such as those indicated above, there were early methods of embroidery which resulted in *lace-like* fabrics, and these often mislead the investigator. For example, fifteenth and even fourteenth century darning on handmade net has a *lace-like* appearance, but *quâ* method neither it nor ancient Oriental whipped and pulled thread work is technically allied with the methods of twisting, plaiting and looping threads. However, Dr. Verhaegen's synopsis of successive styles of lace is at least useful and suggestive, although one may not always agree with him in his classification of certain work. The results of his researches into the local history of Belgian lace-making are of special value, and tempt one to hope that he may pursue them with as much ardour as Mlle. Despierre displayed in collecting data for her volume on Alençon needle-made lace, published some twenty-five years ago.

Chapter II. shows where and how the Belgian industry is being pursued. The latest available statistics give a total of 47,571 lace-makers in Belgium, of whom 25,547 were in Western Flanders and 18,199 at least in Eastern Flanders.

Chapter III. is on manufacturers (*fabricants*)—under which title are included large dealers who get their stocks of lace from local agents or dealers, are sometimes employers of workers, and are both wholesale and retail distributors; other "fabricants" in a smaller way of business are themselves lace-makers, keeping shops, dealing with local lace-makers to some extent on the "truck" system, and selling to both the trade and to private customers. It is difficult, as Dr. Verhaegen remarks, to differentiate *fabricants*, *intermédiares* and *dentellières* who act as *fabricants* and *intermédiares*. Convents undertake the work of *fabricants* and *intermédiares*, and conduct the training of children and adults in the art of lace-making.

Chapter IV. is devoted to a discussion on trade, of which the foreign is the more important, and on competition as between Belgium and other countries as well as that between hand and machine-made fabrics. Under Chapter V. the different classes of *intermédiares* (distributors) are described. Chapter VI. deals similarly with grades of workers and apprenticeship. Chapter VII. treats of technical instruction as supplied through some 160 lace-making schools, the better of which are administered by conventual communities. Chapter VIII. reviews the fluctuations of the earnings of the lace-makers, and supplies interesting statistical tables setting out rates of payments under various conditions, *e.g.* for home-work done by individuals in their cottages; and for work done by groups of workers in organised work-rooms. The grinding oppression under the truck system, which luckily is not really widespread, is exposed by Dr. Verhaegen, who sums up in his last two chapters the features of the present state of the Belgian industry and of its future possibilities. Practically all that he says is germane to the industry as followed in England, Ireland and France. Amongst circumstances which have impressed themselves on him are (1) the decline of fine and elaborate lace-making by hand which is concurrent with the perfecting of methods of making lace by machinery; (2) the ignorance that prevails in the matter of lace designs for hand-work; (3) the shrinkage in various districts of the number of workers; (4) the increase in the number of centralised workrooms where groups of workers are employed under continuous supervision; (5) the number of intermediaries for buying and distributing lace—as many even as four and five stand between the *dentellières* (lace-makers) and the customer who wears the lace—a condition

Hosted by Google

that causes frequent reclamations for improved wages.

It will thus be seen that much material has been carefully gathered together, examined, arranged and presented in a way that has been rarely adopted in regard to industries of far greater extent and importance than lace-making by hand. Dr. Verhaegen's admirable book should be most welcome to every one who is interested in the industry, whether as a manufacturer, a dealer, a weaver, or collector of its productions. Official bodies such as the county councils of Bedfordshire, Buckinghamshire, Northamptonshire and Devonshire, as well as various local committees and associations engaged in fostering the industry in this country, will find it well worth their serious study.

CORAL FISHERY IN JAPAN.

A report from the Italian Legation at Tokio gives some interesting information respecting the coral fishery in Japanese waters, and its influence on the coral industry in Italy.

Until quite recently the principal supply of the raw material was obtained by the Italian manufacturers of coral ornaments from the fisheries in the Mediterranean. These reefs, chiefly situated off the coasts of Sicily, Sardinia, Tunis, Algeria and Spain, have become practically exhausted, and Italy is now almost entirely dependent on Japan for the supply of the unworked material.

The principal market for the raw coral is Osaka, but most of the buyers, who are all Neapolitans, reside at Kobé, and resort, during the busy season in the spring and autumn, to the fishing grounds to make their purchases. Much rivalry exists amongst these buyers, which has the effect of keeping up the prices.

The import trade has also been much hampered by the increased duty now levied, amounting to 40 and 50 per cent. *ad valorem*, on coral goods entering Japan, which practically prohibits the return of the manufactured article to Japan. In fact, the value of these goods imported to Japan in 1909, which amounted to 68,640 lire (£2,745), fell the following year to 46,000 lire (£1,840), after the application of the new tariff.

The quality of the coral which is very plentiful in the seas of Japan, especially on the southern coast, varies very considerably, and is classified principally into *bello*, and *barberia*, red and white, with innumerable subdivisions, depending chiefly on grade of colour.

The quality known as *bello* is the most prized. It is worked chiefly at Naples, and at Torre del Greco, where the best class of articles are made to supply the American and principal markets of Europe. The prices vary from 15 to 30 lire per gram (about £17 to £34 per ounce avoirdupois).

The coral of the *barberia* type is in demand in certain regions in Italy, and is used principally in Romagna and the Marches for peasant jewellery.

The white coral, which is the commonest, and the red, which is subdivided into two qualities known as *mercantile* and *rosso cupo* (or dark red), is chiefly worked at Leghorn, and supplies the Indian market as well as those of Asia Minor, Russia, and Africa.

The value of coral is very variable, and depends on a variety of circumstances.

During 1911, the prices paid for the commoner sorts fluctuated between 5 lire and 600 lire per kilog (between 2*s.* and £11 per lb.), whilst the better kinds (of choice colour) realised as much as 50 lire to 5,000 lire (£1 to £100 per lb.). The production of coral in Japan varies considerably from year to year. Commencing with 1905, previous to which no statistics are available, the output was as follows :—

	Kwan.*	Yen.†	English lbs.	£ Sterling.
1905 . .	9,961	320,181	52,437	32,018
1906 . .	13,184	553,141	109,111	55,814
1907 . .	4,203	371,308	34,784	37,131
1908 . .	7,473	641,776	61,846	64,178
1909 . .	11,172	1,099,101	92,459	109,910
1910 . .	3,539	488,350	29,289	48,835

The coral fishery of Japan employs upwards of 900 boats, manned by four to five hands each. The appliances for dredging are very rude and primitive, and the fishermen have no particular skill in this branch of industry, and are engaged in ordinary fishing when not employed at this work.

None but Japanese subjects (who must first obtain a permit from the local authorities) are allowed to engage in coral fishery.

CULTIVATION OF VIOLETS AT HYÈRES.

Violets are cultivated on a large scale in many places on the French Riviera, but more particularly in the neighbourhood of Hyères and Grasse. The violets of Hyères enjoy a good reputation on account of their sweetness and beauty, and are in great demand by florists all over Europe. Large quantities of bunches of these flowers are sent away by post daily during the winter months from Hyères to most of the principal towns in the north of Europe. The violet appears to thrive well in the soil of argillaceous schist, which covers the greater part of this district; it also grows well in the alluvial lands near the rivers, and even the sandy tracts close to the sea yield good crops of this flower.

The ground for growing violets requires to be well prepared, by ploughing or digging, to a depth of 14 to 16 inches, and also to be well manured.

The beds are generally laid out in ridges and furrows, possibly running from east to west, about 2 ft. apart. The violets are planted on the northern slopes, and are sown with dwarf peas. During the winter the plants require to be sheltered from the cold north winds by a covering of mats or hurdles. These are sometimes made of

* Kwan = 8·276 English lbs. † Yen = about 2*s.* 0½*d.*

Hosted by Google

cane or reeds, or of dry bunches of heather supported by a double row of stakes driven into the ground about 5 ft. apart. The stakes are 3 ft. high on the north side, and 5 ft. to 6 ft. on the south. These rows of sloping hurdles, which act as wind screens, are about 20 ft. apart, and do not prevent sufficient sunlight during the day from reaching the plants, or interfere with the picking of the flowers.

The violet beds last about five or six years, after which they must be ploughed up and prepared for other crops, as the ground becomes exhausted, and a period of seven to eight years is usually allowed to elapse before making a fresh plantation in the same place.

In dry weather the plants require abundant watering. The dwarf peas should be followed by salads and other crops, so as to afford partial shade to the flowers.

The principal kinds grown in this district, all of which are varieties of the common sweet violet (*viola odorata*), are the *Luxonne*, which bears a profusion of large, finely-scented flowers, of a brilliant violet colour; the *Princesse de Galles*, with an abundance of dark mauve blooms; the *Wilson*, a pale blue early flowering variety; *Le Czar*, very vigorous, with long-shaped blue flowers. Three other varieties have also been recently introduced; they are: *Madame Fichet-Nardy*, very prolific, with dark-blue flowers; *Souvenir de Madame Josse*, with fine large flowers of a reddish mauve, with white centre; *Madame Schwartz*, with large flowers of a fine violet colour.

The flowering lasts all the winter—from the beginning of November to the middle of April. The gathering is chiefly done by women and young girls, mostly Italians, who arrive in large numbers in the autumn from distant parts of Italy for the purpose, returning home as soon as the work is over in the following spring.

A good deal of skill is required for picking and making up into bunches, which contain on the average fifty-five to sixty separate flowers.

A good picker should make from 250 to 300 bunches per day, which, paid at the rate of 1.25 francs to 1.50 francs per 100, would mean from 3 francs to 4½ francs (2*s.* 6*d.* to 3*s.* 9*d.* per day). Towards the middle of March, when the flowers are very plentiful, they are gathered without the stalks, and are sold to the manufacturers of perfumes at the rate of 1.25 francs to 1.5 francs per kilogram (5½*d.* to 6¾*d.* per lb.). A large number of children are paid from 20 to 30 centimes per kilogram (1*d.* to 1½*d.* per lb.) for this work, which requires little skill.

For export the bunches of violets are carefully packed in specially made baskets of split cane or osier, 20 ins. by 12 ins. and 7½ ins. deep. They usually contain sixty-four bunches, and occasionally as many as seventy-two, carefully arranged in four layers. The baskets are first lined with oiled paper. In very cold weather, and when sent to northern countries, the baskets require a covering also of thick grey packing paper, in order to preserve their contents from the frost. The weight of these baskets, which are sent away by parcels post, does not exceed 5 kilograms (11 lbs.). The prices on the spot vary very considerably according to season, between 10 francs and 25 francs being usually paid per 100 bunches, except at Christmas and the New Year, when they fetch as much as 35 francs or even 40 francs (28*s.* to 32*s.*) per 100 bunches.

On the northern markets the prices are very uncertain, and range between 30 francs and 60 francs (16*s.* to 48*s.*).

ITALIAN TRADE WITH PANAMA.

The Italian Consul at Panama, in an exhaustive report, points out that Italy is far behind other countries—notably the United States, Great Britain, and Germany—in finding a market for their produce in that Republic.

The imports to that country, which are chiefly manufactured goods and foodstuffs, amounted in value, in 1910, to upwards of ten millions of balboas* (about two millions sterling), half of which was for goods imported from the United States (not including the value of material for the construction of the Canal), whilst the remainder was paid chiefly to Germany and Great Britain. Judging from the following list of some of the principal articles imported, it will be seen that Italy takes quite an insignificant part in the trade with Panama.

Cotton Goods.—Imported in 1910 to a total value of 847,513 balboas (£176,560), to which Italy only contributed to the value of 15,677 B., whilst the imports from the United States amounted to 236,265 B., Germany 57,468 B., and Great Britain 514,796 B.

Boots and Shoes.—Total value of imports, 517,286 B. (£107,768). Italy 495 B., United States 494,917 B., Great Britain 9,062 B.

Ready-made Clothing.—Total 498,560 B. (£103,866). Italy 7,964 B., United States 288,237 B., Germany 28,023 B., Great Britain 111,015 B.

Chemical and Pharmaceutical Products.—Total 440,931 B. (£91,860). Italy 7,599 B., Germany 28,511 B., United States 184,826 B., Great Britain 46,790 B., France 29,860 B.

Rice.—Total 334,774 B. (£69,745). Italy 375 B., Germany 205,254 B., Great Britain 110,424 B.

Woollen Goods.—Total 197,250 B. (£41,093). Italy 2,648 B., United States 5,195 B., Great Britain 179,340 B.

Condensed Milk.—Total 179,087 B. (£37,620). Italy 16,836 B., Germany 108,317 B.

Furniture.—Total 168,099 B. (£30,020). Italy 84 B., United States 136,912 B., Germany 17,617 B., Great Britain 11,062 B.

Olive Oil.—Total 126,368 B. (£26,326). Italy 8,491 B., United States 101,899 B., France 12,960 B.

Wine.—Total 108,924 B. (£22,692). Italy 5,472 B., United States (California) 22,981 B., France 51,598 B., Spain 24,532 B.

* The balboa equals 4*s.* 2*d.* English money, or about an American dollar.

Hosted by Google

Butter.—Total 78,214 B. (£16,294). Italy 2,734 B., United States 14,207 B., Germany 26,567 B., Great Britain 20,509 B.

Straw Hats.—Total 77,440 B. (£16,133). Italy 6,065 B., United States 28,334 B., Great Britain 32,456 B.

Amongst other articles imported may be mentioned *Perfumery* to the total value of 66,450 B. (£13,844), of which Italy supplied only to the value of 671 B. *Stationery* 48,063 B. (£10,013), to which Italy 271 B. *Cheese*, total 45,022 B. (£9,384), Italy 4844 B. *Felt hats*, 37,478 B. (£7,808), Italy 2957 B. *Preserved fruit*, 28,871 B. (£6,015), Italy 819 B. *Candles*, 27,528 B. (£5,735), Italy 20 B. *Mineral water*, 22,575 B. (£4,753), 934 B. from Italy. *Parasols*, 21,892 B. (£4,560), 4,421 B. from Italy.

The total value of the exports from Panama in 1910 amounted to 1,769,330 B. (£368,602), and were as follows:—

	Tons.	Value in Balboas.
Germany	770	93,669
United States	125,321	1,508,422
France	55	1,966
Great Britain	185	165,273
	126,331	1,769,330

The exports to Italy were nil, although a profitable trade might be done in mother-of-pearl, vegetable ivory, and fancy woods with that country.

Some of the principal articles exported from Panama in 1910 were:—

	Tons.	Balboas.	£ Sterling.
Bananas (2,643,900 bunches)	114,945	921,289	191,935
India-rubber	154	170,721	35,566
Gold in bars	$2\frac{3}{4}$	134,975	28,120
Vegetable Ivory	2,105	132,635	27,632
Raw hides	565	84,864	17,680
Mother-of-pearl Shells	625	50,914	10,607

Together with tortoise-shell and live turtle, cacao, medicinal plants (sarsaparilla, ipecacuanha, copaive, etc.), mahogany, and fancy woods, etc.

FRENCH INDUSTRIES CONNECTED WITH THE CHAMPAGNE TRADE.

There are in the district of Rheims many enterprises which, while only accessory to the principal industry—that of champagne making—are quite important in themselves. Chief among these auxiliary industries is the manufacture of champagne bottles, whose production is fraught with many difficulties. The champagne bottle has to be constructed in all its parts of an almost mathematically even and heavy thickness; its glass must be perfectly smooth and unaffected by the acids contained in the wine; its neck must be exact in every particular, to insure perfect corking, and with no grain or projecting points on the inside. So much progress has been made within the last ten or fifteen years, that where formerly a breakage of 5 per cent. was considered very small, at the present time the average breakage does not exceed 1 per cent. Despite the perfection as to strength reached in the production of champagne bottles, the strain upon them caused by the pressure they sustain and the repeated handling they undergo, weakens them to such an extent that it is considered unsafe to use the bottles a second time. With the exception of smaller houses making the cheaper brands, champagne manufacturers place their wine in none but entirely new bottles. The United States Consul at Rheims says that four glass-blowing establishments in that city, of which one is among the largest in France, and several others in the vicinity of Rheims, make almost exclusively bottles for champagne. They work night and day, in three shifts of eight hours each, and turn out about 40,000,000 bottles annually. The men performing this difficult work are well paid. Another important industry entirely dependent on the wine trade is the manufacture of corks for champagne bottles. The material for these corks is principally imported from Spain, in which country is found a tree whose bark is resistent enough to permit of its use for this class of corks. The work of dressing and testing the bark, and completing the cork, is in the hands of very skilled workmen at Rheims, most of whom are well-paid Spaniards. Since it is very difficult to procure a bark thick enough to make a good cork out of a single piece, a number of the corks made nowadays are composed of two pieces of thin bark pasted together lengthwise. This process of pasting the pieces together is patented, and since the corks thus made seem to answer in every respect the demands made upon them, a number of cork manufacturers are now working under this patent, and apparently with considerable success. There are about twenty cork manufacturers in the district of Rheims, turning out annually one hundred million corks, of a value between £280,000 and £310,000. Local woodworking establishments supply the champagne houses with the boxes in which the wine is shipped to foreign countries. These are made in a mechanical way, and while they are very substantial they are of a superior finish, and afford remunerative occupation to many workmen. Several large willow-work manufacturers furnish champagne houses with the baskets in which the wine is forwarded to places in France and in near-by countries. Several firms make a speciality of the straw covers in which the bottles are encased before being packed in boxes or baskets; the straw used for these covers is cut and sewn by machinery. This industry encourages the cultivation of rye in the neighbourhood of Rheims, the straw being used for the manufacture of the covers, and the rye sold to other countries, mostly to Germany. Two firms in Rheims and four at Epernay construct special machinery for the manipulation of champagne, such as automatic bottling machines, machines for cleaning, for corking and uncorking, for wiring bottles, etc. Presses for extracting the juice from the grapes are made by several large houses in Rheims and the neighbourhood. One

Hosted by Google

important house makes a speciality of manufacturing metallic capsules and tinfoil for champagne bottles, and numerous lithographic establishments are engaged in producing artistically decorated labels. It is safe to say that the above-mentioned industries give employment to more than 5,000 skilled workpeople. For their future prosperity much depends upon abundant harvests of grapes, the crops during the last five years having proved to be so insufficient that only several good years will prevent the champagne trade and its auxiliaries from suffering a very severe setback.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

Automatic Looms.—Until a very recent date such progress as has been made with self-feeding looms in this country had been entirely in the cotton business. Even there the adoption of them has been significantly small, and it is estimated that only one loom in seventy-five in Lancashire is of the automatic type. There are about 10,000 at work in this country and about 220,000 in the United States. The contrast has been made a reproach to British manufacturers, but judgment cannot be given on the statistical appearances alone. The ring-spun American yarn is more suited than the mule-spun English to the necessities of the case. The American cloths lend themselves better to automatic weaving, and the Americans have had besides the incentives of dear and scarce labour. If Lancashire manufacturers have not adopted the loom largely they have at any rate considered its claims and advantages. The automatic loom of the self-filling and self-stopping type is now on its trial in the worsted industry, and the principal beginning has been made in a district in which weaving prices are much higher than in the surrounding area. Huddersfield, where the system of one loom one weaver obtains, has lost the trade in cheap worsted coatings to Bradford, where weavers mind two looms and work for materially lower wages at that. With the automatic machines one weaver superintends six looms in Huddersfield, and the work is so divided that the weaver gives her whole attention to the cloth; all carrying and filling of magazines is done by helpers, and all adjustments of the looms are made by men. With this aid it is hoped to win back some of the business in cheap, plain goods. The worsted looms are broad and heavy, thus differing from the cotton looms of which some weavers in America can mind twenty-six at one time. The first cost of automatic looms is two or three times that of ordinary ones, and in general more waste of yarn is generated in weaving; but it is understood that in Huddersfield practice the waste has been reduced to a minimum, and the output is some 90 per cent. of the possible efficiency. For at any rate ten years inventors of automatic looms have been knocking at the doors of worsted manufacturers, but hitherto there has been no considerable practical success with their inventions.

Profits and Turnover.—Explanations of the comparatively poor profit shown by the Calico Printers' Association will doubtless be furnished in due course. Meantime the question whether shortage of production is the responsible cause rests unsolved. In the case of any of the large concerns principally engaged in treating upon commission material the property of other persons, the fullness of the output is of vital importance to the financial result. The spinner or manufacturer may redeem a slight slackness by a fortunate transaction in his prime material. The bleacher, dyer, or printer, tied to a fixed tariff of prices, is helplessly at the mercy of the volume of work. With a production, say, of 80 per cent. of the maximum he may just hold his own; with 75 per cent. he loses an appreciable lump sum; with 90 per cent. he probably nets a large sum of money. The natural effect of narrowing profit margins is to impose a great strain upon the maintenance of output. Once the standing expenses are submerged the excess takings are virtually all profit; but much work has to be done before these more or less permanent costs are covered. Company directors do not ordinarily publish the intimate facts of their trading, but there have been admissions showing the fluctuating character of the business of calico-printing for the market. For example, there have been gains of £15,000 in one year in one works and a dead loss of money in the next. Similarly, in the dyeing trade it is known that branch works of large combines will make £20,000 to £30,000 in one year and only one-tenth as much in the next, the prices for work done being meanwhile unaffected. Of course it pays individuals to make sacrifices to get the last ounces of turnover, but the cutting of prices reacts upon prices at large and intensifies the struggle ultimately. High prices may afford some remedy, and it seems that an attempt to establish them is to be made by the Calico Printers' Association in conjunction with the leading printers outside that combine. The Association comprises nearly fifty printworks which had originally 830 printing machines, and its capital is over eight millions.

Lithographic Calico-printing.—It is reported that there is to be a considerable extension in Lancashire of the style of calico-printing now carried on at Letchworth in a comparatively small way. In this process the cloth is printed in oil colours upon what is substantially a rotary lithographic machine resembling some used in printing upon paper. Instead of the engraved copper rollers of the regular calico-printing machine, grained metal rollers are employed. The design is transferred to the surface of these from the original plate, the rollers are inked with a colour made sufficiently fatty to repel moisture, and designs in three and four colours are printed at one passage through the machine at a rate said to be eighty yards a minute. The pigments are more

Hosted by Google

expensive than the thickened dyes ordinarily used, but the need for steaming, washing, and finishing is avoided. The process is over when the ink has dried; or at most, no more is necessary than a quick run through a cloth-mellowing machine to break up any caking of colour on the surface.

Human Hair.—The uses of human hair in making such adornments as wigs or hair-nets are better recognised than its strictly textile employments. The material is too coarse and unkind to replace wool in any of the finer services, but in conjunction with other ingredients it is used in making filter-cloths for oil-presses, and might conceivably be used in making canvas interlinings for coats. The staple article comes in the form of plaits from China, and can be seen occasionally in quantities of hundreds of bales. The hair is washed mechanically and put into the form of sliver for drawing and spinning on worsted frames. In its raw state the hair contains liberal proportions of sand.

Mill Lighting.—It is to be inferred from the publication of a factory inspection report on the subject that the internal illumination of mills is to receive more official attention. The *desiderata* laid down by the chief inspector—viz. (1) window space equal to at least one in ten of the floor space; (2) the windows to command a large sky area—admittedly cannot be met in side-lit rooms. Weaving sheds with saw-tooth roof lighting generally comply with the rate of efficiency named, but manufacture cannot economically be carried on in single-storey edifices in this country. Spinning, and the processes anterior to spinning, are conducted almost solely in rooms lit from the sides, and in these places the recommendation is to dispose the machinery in such a manner as not to obstruct the passage of daylight towards the centre of the room. The great expanse of window is the striking feature of the new standard pattern of cotton-mill, and worsted spinning mills embodying the same feature are already planned. Small pyramidal panes, intended to pass the rays of light in horizontal lines, have had to be used in some of the large side-lit mills built in America. In that country, too, much trouble has been spent by electrical engineers in devising means of soft and uniform artificial illumination and in explaining the merits of their respective systems. The matter promises to become of more moment in England, where there are still an excessively large number of mills ill-lit totally or in odd places. Darkness plays its part in creating accidents to the person as well as in impeding work, and bad lighting is a stock complaint of some of the cotton operatives' representatives in Parliament.

Collective Agreements.—Textile opinion is predominantly in favour of collective agreements between employers and workpeople in those districts in which workmen are closely organised. The mind of the cotton trade, expressed in the famous Brooklands Agreement, has been made up more than twenty years. The Bradford Dyers' Association is firmly in favour of agreements of its own which have subsisted some ten or twelve years. Newer converts, like the Huddersfield woollen manufacturers and spinners, are only anxious for powers to compel the non-associated employers to observe any arrangement into which a certain majority enter. Where all the men and all the masters are in their respective organisations the case is relatively simple. Otherwise the non-assenting parties are much in the position of those free-lances who hang upon the flanks of the Masters' Federation of Cotton-spinners and run their mills full time when the federated employers are sacrificing themselves temporarily to curtail the consumption of cotton and the gross production of yarn. There are still considerable tracts of textile manufacturing country which barely know either trade unionism or the federation of employers, and in these no question of collective bargaining arises. Again, as in the woolcombing industry, where a weak or ill-managed union has held the field, agreements have been followed by repentance and refusal to continue.

Household Novelties.—The ordinary textile manufacturer is too far engrossed in the production of goods in bulk to spare much attention to the small and sometimes lucrative articles of novelty that can be made out of suitable cloth. Such an article is the American "notion" known as the dustless duster. It proves on examination to be a square of flimsy unsized cotton muslin, made from single yarn and dyed with aniline black. The fabric in its natural condition would seem to be well suited for picking up and retaining loose dust, and this aptitude has been improved by a faint impregnation of what may possibly be a rather heavy petroleum oil. There are, doubtless, alternative means of treating muslin to make it more retentive. The commercial potentialities of a duster which neither loses its burden of dust nor requires periodical shakings at the window may be admitted, and the first cost can hardly be great. Since the invention of polishing cloths made from unfinished cotton velvet of a particular quality, there has been little to show in this direction. Silk-waste polishing cloths, resembling those used as sponge cloths for machinery, apparently do not command any extensive domestic sale, although their properties are excellent and the cloths cheap.

ARTS AND CRAFTS.

National Competition and its Future.—The exhibition of works which have gained awards in the National Competition has been open all through August at South Kensington. It will be remembered that this is said to be the last year when the National Competition under the existing regulations will be held. However that may be, and whatever changes the future may hold in store, the prevailing opinion seems to be there will almost

Hosted by Google

certainly be an exhibition of approximately the same kind held in London next year, whether under the same or rather different designation and conditions. Undoubtedly this year's work made one feel that it would be a great loss if the exhibition were to be discontinued—though it is easy to think of minor ways in which the show might be improved. To begin with, it cries aloud for better housing. It is not merely that the approach to the iron shed in which the works have been exhibited for years past is, to say the least of it, bad; but that even when you are inside this temporary building you find yourself in a most unsuitable exhibition gallery, as unsatisfactory in its lighting as in its ventilation. Again, there is a certain proportion of work shown which makes one think that the executant has spent an amount of time on it altogether out of proportion to its real educational value—time which could, and probably would, have been employed to greater advantage had the student been intent on acquiring useful knowledge or skill rather than on gaining medals.

The really crying need, however, is for a final revision of the awards. The various subjects are very rightly and properly judged by different groups of artists, all of them competent men, many of them the foremost representatives of their own branches of art. They do their work thoroughly and conscientiously, but they are men of widely different standpoints and temperaments, and they judge leniently or hardly according to their own natural tendencies. The result is that the standard of award for different classes of work varies in some cases very considerably, and, since the same examiners go on often for quite a number of years, students get into the habit of avoiding certain subjects in which for some years no high award has been made, and crowd to certain others in which the examiners are particularly kind hearted, and are rather lavish with prizes and commendations. So it happens that certain subjects get a bad name: the best students leave them on one side, and it comes to be a generally understood thing that, say, a bronze medal is the highest possible award to be expected in that particular subject. Now, all that is very natural, and the kind of difficulty that is bound to arise. The mischief is that it is more often the designs for fairly important manufacturing processes that get hardly judged than work which, from the point of view of the nation at large, is relatively unimportant. If only after the different kinds of work had been judged by the various little groups of examiners, the judges as a whole could run through the prize works, the differences of standard would be visible to them at once, and, with a very little trouble and a reasonable amount of give and take on the part of the artists responsible, could be easily and quickly adjusted and righted. As it is, the men who have conscientiously refused to give prizes to work which they did not consider up to the mark are by no means pleased when they see students in another class getting bronze medals for work which in their class would not receive more than a commendation.

This Year's National Competition Exhibition.—One of the most cheering features of this year's exhibition is the improvement in the studies of historic ornament. Students have been understanding how to treat this subject better for some years past, but this year they seem to have realised more fully than before the purpose of studies of the kind, and to have taken pains to choose good models and to render them intelligently, showing what is really needed without undue elaboration. The set of textile studies by Louis S. M. Prince, of Manchester, was extremely good in this last respect, and there were two groups of studies of initial letters and MSS. which were excellently chosen as types. This is peculiarly satisfactory, as it tends to show that more attention is being paid to the study of historic ornament than was the case a few years ago.

Considering how important the study of plant form is to the designer, and how large a proportion of modern designs are naturalistic in character, it is rather discouraging to note that, in spite of a good many clever drawings of plants, there are very few which are treated with any idea of their suitability for subsequent use. Again, in the subject known as "Plant and three designs," while the study from nature is often quite well done, the students seem to show very little power of turning their studies to account, and the designs ostensibly based upon the drawings which accompany them too often bear little or no relation to them. It looks as though teachers were hardly aware that it is just at the point when it comes to rendering natural forms with a certain amount of convention that students generally want a little help and direction. They are apt either to think that a study from nature is practically a design, or, on the other hand, to produce a pattern in which the main characteristics of the plant are lost.

When we turn to the repeating patterns for various processes of manufacture, though there is nothing very startling, the work reaches a very creditable level of accomplishment, and the patterns as a whole are free from the disfiguring mannerisms so common a few years ago. There seems, however, a regrettable tendency to do work on a scale which is rather wanting in boldness. The wallpaper designs are decidedly poor. Whether the recommendations of the examiners, who wish to encourage the introduction of animal forms, and at the same time draw attention to the fact that students should not forget that paperhangings are intended for backgrounds, will produce better results next year remains to be seem. The designs for pottery and glass are less noteworthy than those submitted for the last few years, but the stained glass by Harry Clarke, of Dublin, to which a gold medal was awarded, was peculiarly jewel-like in colour, and shows a true appreciation of the qualities which go to make a good window. In the case of the smaller

Hosted by Google

craftwork, one cannot help being struck by the improvement in technique which has taken place since objects of this kind first began to be included in this exhibition. The butterfly design for an enamelled silver cloak-clasp set with topaz, by Dorothy V. C. Monro, of Islington (Camden School of Art), which received a gold medal, is conceived with a good deal of imagination and carried out with skill. The wooden caskets—one to hold a presentation key, carved in French walnut by Alice L. Hitchcock, of Kensington (School of Art Woodcarving Art Classes), and the other of stained wood to hold playing cards, by Esther N. Brown, of South Marylebone (Polytechnic School of Art), which also gained gold medals, are both in their different ways very satisfactory pieces of work. The leatherwork, again, has improved greatly of recent years, though the leather book-covers are rather wanting in originality. It seems, as the examiners point out, a pity that students do not turn their attention to the designing of publishers' book-covers, for which there must be a far larger demand. Of illumination and lettering, there is a very good display. The embroidery, though it reaches a respectable level, is not particularly remarkable.

The exhibition, taken as a whole, must be looked upon as decidedly satisfactory. It displays a very creditable amount of skill and of designing power, and is far more interesting than the shows of a few years ago. The only really disturbing feature about it is the relatively large proportion of good craftwork and the comparative neglect of design for the larger manufacturing industries. This weak point seems to be recognised by the examiners and the authorities generally, and it is to be hoped it is only a phase which will soon pass away.

The Royal College of Art Exhibition.—When one crosses the road from the National Competition to the Royal College of Art, one cannot but feel that, so far as design and craftsmanship are concerned, it will be some time before the college really attains the position which it is intended to hold of a kind of university for art. It is not that the work of certain individual students is not up to the mark, but that, taken collectively, the productions fall far short of the best national competition standard. When one reflects how large a proportion of students at the Royal College are national scholars or exhibitioners, men and women who have gone through other schools in London or the provinces, and done conspicuously well there, it is rather disappointing to find that they do not turn out better, more interesting, and more individual work, when they get to the college. It is easy to understand that, at the first start, the wealth of material in the museum may prove somewhat overwhelming to the student from the provinces, that his work for a few months should really seem to go back rather than forward—but this should be merely a stage in his development, and not a permanent effect.

OBITUARY.

Clinton T. Dent, M.A., F.R.C.S.—Mr. Clinton Thomas Dent, the eminent surgeon, who had been a member of the Society since 1889, died on the 26th inst. at his house in Brook Street at the age of sixty-two. Mr. Dent was educated at Eton and at Trinity, Cambridge, and became a Fellow of the Royal College of Surgeons in 1877. He held a number of important appointments in connection with St. George's Hospital, the Royal College of Surgeons, and other medical institutions. He was also chief surgeon to the Metropolitan police. He was the author of several well-known surgical works, and contributed many articles to the medical publications.

He had a great reputation as an Alpine climber, and was a very active member of the Alpine Club, of which he was at one time president. He wrote much and well on Alpine subjects, and climbed in the Caucasus as well as in the Alps. He took a leading part in investigating the fate of Donkin and Fox, who were lost in the Caucasus in 1888. In 1897 he gave the Christmas juvenile lectures on "The Growth and Demolition of Mountains"—the scientific side of the pursuit which he had made the amusement of his life. He was very popular in a large circle of friends, to whom the announcement of his unexpected death will have come with somewhat of a shock.

GENERAL NOTES.

Mathematics and Engineering.—At the International Congress of Mathematicians, which has just held its meeting at Cambridge, Sir William H. White delivered a lecture on the place of mathematics in engineering. He said that the foundations of modern engineering had been laid on mathematical and physical science, and the practice of engineers was now governed by scientific methods applied to the analyses of experience and the results of experimental research. Notable achievements were accomplished in the last century by men whose mathematical and physical knowledge was small, but their successors enjoyed greatly superior educational advantages. The fundamental idea underlying the now accepted system of training engineers consisted in the combination of an adequate knowledge of the sciences which bore on engineering with a thorough practical training in actual works. In particular, an adequate knowledge of mathematics must be possessed by every educated engineer, because he thus acquired valuable tools by which he might overcome difficulties otherwise insuperable, as well as invaluable habits of thought. Some authorities now favoured special courses in "practical mathematics"; others believed that engineers should be taught by professional mathematicians, because this method must

Hosted by Google

lead to broader views and greater capacity for original investigation. His experience led him to rank himself with the supporters of the latter view, and this view had now been adopted at the Imperial College of Science and Technology.

Victoria and Albert Museum.—Several acquisitions of considerable importance have recently been made in the Department of Metalwork. Among these is a small pendent reliquary in the form of a plaque, with a figure of St. Catherine in brilliant translucent enamel on silver, set in a silver-gilt frame. It is probably the work of a craftsman of Cologne in the late fourteenth century. An Elizabethan tazza is the most remarkable of recent additions to the collections of English silver. The tazza is in silver-gilt, the foot is finely *repoussé* and chased with masks and groups of fruit, the bowl is engraved with arabesque foliage, and has a raised boss in the centre which is decorated with the head of a warrior. It bears the London hall-mark for 1564-65, and the design shows the influence of the German craftsmen who were working in England during the sixteenth century. Of three examples of Continental silver, the most important is a reliquary of silver-gilt, elaborately chased. The panels on its base are decorated with foliage, and on two of them are heads which may possibly be portraits of the donors. This reliquary is a magnificent example of the best period of Spanish work in silver, the first half of the sixteenth century; and the maker's mark beneath the foot appears to connect it with the celebrated Arphe family of silversmiths. Two examples of Continental silver are a French incense-boat of the fifteenth century of graceful outline, and a silver-gilt cup and cover of about the middle of the sixteenth century. The foot of the latter bears the Strassburg mark, and it is valuable not only for its own beauty of design and workmanship, but also for comparison with English work of the period. Among other objects recently acquired, the most important is a salt-cellar of 1664, which was formerly on loan in the museum, and is well-known to collectors. It is square in plan, with an elevation somewhat in the form of an hour-glass, and has four scroll-work arms projecting from the upper surface. Plain salt-cellars of a similar type are in the possession of Winchester College, the Clothworkers' Company, and the Corporation of Portsmouth; but the example acquired by the museum is distinguished from them by its decoration of acanthus foliage which is carried out in the rich style of the Restoration period. It represents the last form of the ceremonial salt-cellar which was finally to disappear before the beginning of the eighteenth century. Two other recent acquisitions of English work may be mentioned. One is a plain two-handled cup and cover made by Richard Bayley, and bearing the London hall-mark for 1719-20. The other is a steel key with delicately chiselled and engraved barrels and wards, and a pierced bow with the crowned cipher of William III. The key is a fine example of the work for which English smiths at the end of the seventeenth century were renowned. The Department has also acquired a pair of candlesticks of silver cast and chased, which bear the Paris mark for 1714-15, and are examples of the finest work of the time. This acquisition is of special importance as the museum is not rich in French silver, although it has the advantage of the loan of a fine series from that generous benefactor to the museum, Mr. J. H. Fitzhenry. Of other examples of Continental work, the most noteworthy is a charming example of a pectoral cross in silver-gilt; it is German of the fifteenth century, and probably once contained a piece of the true cross.

Commerce of Madeira.—The report of the Italian Consul at Funchal states that the total value of the exports and imports at this port, which in 1910 amounted in value to 3,760,030 milreis* (£835,562), was only 1,890,748 milreis (£420,166) in 1911. This shows a decrease of 1,869,282 milreis (£415,396) as compared with the trade of the previous year. No reason is given for this falling-off. The principal articles imported at Funchal were coal, woven fabrics, wine, maize, corn, rice, sugar, tea, molasses, dried cod, cheese, timber for building, candles, petroleum, etc. The exports in 1910 consisted chiefly of embroidery, wine, tunny in oil, fruit and early vegetables, basket-work to the total value of 929,092 milreis (£206,465). The trade is chiefly in the hands of English and German firms established in the island. Forty sailing vessels and 983 steamers called at this port during last year; none of these were of Italian nationality.

The Refrigerating Industry in Italy.—On January 1st of the present year there were twenty-one public companies (*Società per azioni*) engaged in the refrigerating industry and registered in Italy. The share capital of eighteen of these companies established in Italy amounted to 7,045,585 lire (£281,823), and of one established at Massowa (Eritrea) with a capital of 400,000 lire (£16,000), making a total of 7,445,585 lire (£297,823). Of these twenty-one companies (the capital of two are not given), two are established at Genoa, two at Milan, and two at Naples, where the oldest company, the *Società anomima ghiacciaje e neviere napolitane*, was founded in 1885 with a share capital of 1,100,000 lire (£44,000). The company having the largest capital, viz., 1,300,000 lire (£52,000), is the *Società dei magazini refrigeranti artificiale* (Gondrand Mangilli), of Milan. There are also a large number of works for the manufacture of artificial ice in many towns in Italy carried on by private companies or owners for which no statistics are available. Refrigerating plant is also employed in breweries, cold storage, and in conjunction with other industries.

* Portuguese milreis equals about 4*s.* 5½*d.* English currency, or 4½ gold milreis equal £1 sterling.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

THE LOOM AND SPINDLE: PAST, PRESENT AND FUTURE.*

By Luther Hooper.

Lecture I.—Delivered February 26th, 1912.

Primitive Looms: Prehistoric, Ancient, and Modern.

The spindle and the loom, the one for twisting fibre into thread and the other for weaving the thread itself into cloth, are prehistoric and almost universal tools.

These tools, and the methods of using them, have never been subject to much variation, whether invented by prehistoric man, the skilful weavers of the ancient world, or the ingenious craftsmen of the primitive tribes of to-day.

Moreover, it is not only in elementary forms of weaving that this similarity is found, for if the essential principles of the most modern spinning and weaving machinery be investigated, it will be seen that they are identical with those used in the most ancient times. The complicated textile machinery of to-day is, therefore, simply a natural development from that used by primitive weavers of all time.

In the present course of lectures my intention is to demonstrate the principles of the primitive loom and spindle, and trace their gradual development into the wonderful, but still far from perfect, mechanism of the modern machines actuated by steam power; also to indicate the lines along which textile machinery, in the future, is likely to be improved.

To-night, I shall occupy the time at my disposal by a description of primitive spinning and weaving appliances, prehistoric, ancient and modern.

Prehistoric examples of the weaver's art are extremely rare. This is owing, of course, to the perishable nature of the materials of which they are composed. Few as they are, however, and consisting, as they do, of the merest shreds of textile fabrics, they show unmistakably that the art of the loom, as well as that of the spindle and needle, was understood and successfully practised in what has been poetically called by an eloquent French writer "The night of time."

The term "prehistoric" has, of course, only a relative meaning. Roughly speaking, history begins at the period in human development when the use of metal for tools and ornaments supersedes that of stone. I believe I am right in stating that antiquities of the Age of Stone are classed as belonging to prehistoric time.

It is generally agreed that most of the Lake Dwellings of Switzerland, which were discovered and eagerly investigated during the last century, belong to the neolithic, or later stone period. It was amongst the remains of one of the earliest of these villages, discovered in the bed of the lake at Robenhausen, that bundles of raw flax fibre, fine and coarse linen threads, twisted string of various sizes, and thick ropes, as well as netted and knitted fabrics and fragments of loom-woven linen cloth, sometimes rudely embellished with needlework, were found. There were also spindle whorls and loom weights of stone and earthenware, one or two fragments of wooden wheels, which might have formed parts of thread-twisting machines, as well as rude frames which were possibly the remains of simple looms.

It is remarkable that these relics of primitive weaving were found in the lowest of three

* A large number of the illustrations are taken from Mr. Hooper's "Hand-Loom Weaving," and are reproduced by the courtesy of the publisher, Mr. John Hogg.

Hosted by Google

villages, which, during successive ages, had been built on piles, on a common site near the margin of the lake. The linen shreds bear evidence of having been partially burned, and they were found very deeply buried in the clay which forms the bed of the lake. It has been supposed that this early village was destroyed by fire, and that to this accident we owe the preservation of the precious relics. All traces of actual textile fabrics are absent from the later villages, although loom weights and spindle whorls are found in them all.

This theory of accident may be true or not, but, however the partially-burned specimens of flaxen materials became embedded and preserved, they demonstrate that the people of the Stone Age, in Europe, cultivated flax and hemp, prepared and spun the fibres into continuous thread, doubled and twisted it into various thicknesses for different uses, and netted, knitted or wove it into fabrics of a sort which required a good deal of ingenious contrivance for their production.

Keller's work on the Lake-dwellers of Switzerland is illustrated with a large number of lithographic drawings. I have had a few of these photographed, as they show the construction of the textiles more clearly than photographs of the actual discoloured fragments of cloth and thread would do.

[Photographs of illustrations from Keller's "Lake Dwellings of Switzerland," Longman, 1892, were here thrown on the screen.]

Discoverers of such relics as these are often apt to exaggerate in their imagination the attainments of the people who produced them. Thus, Professor Messekommer, who in 1882 was fortunate enough to find the most important and, probably, earliest of the Lake-dwellers' villages, at Robenhausen, as already described, says that "he is convinced, from the specimens of textiles there found, that all manner of weaving was thoroughly known at the very beginning of the lake-building period." An expert examination of these fragments, however, does not bear out his assumption. They are, as we have seen, all webs of the very simplest kind, and are just such as are woven by savage people of to-day, by means of the most elementary weaving appliances. No traces of tools for textile work were found beyond whorls for spindles, one or two charred spindles with thread wound on them, sharp-toothed combs, which were probably used for preparing the raw fibre, and a few weights of earthenware, similar to those which were used by the Greeks and Romans for weighting the warp threads of their upright looms.

In reconstructing the life and operations of ancient and prehistoric man from the scanty relics which are available, it is most reasonable to imagine that weaving and, in fact, work of all kinds was carried on with the maximum of human craft and patience and the minimum of mechanical contrivances. We should not imagine how quickly and easily things might have been made, but how simply, even though with infinite pains, the work could have been done.

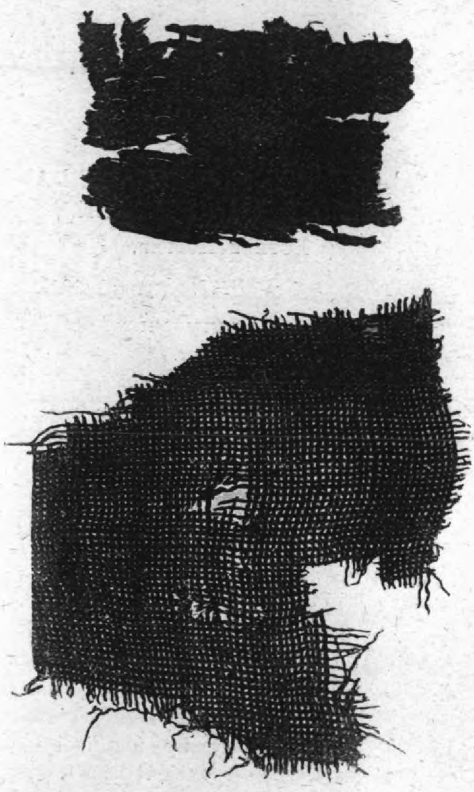

FIG. 1.—FRAGMENTS OF LINEN CLOTH, WOVEN BY THE PREHISTORIC LAKE-DWELLERS OF SWITZERLAND.

Bearing this in mind, let us examine two interesting relics of the handiwork of a prehistoric weaver shown at Fig. 1.

These are not, like so many of the fragments, netted or knitted from a single thread. This is proved by the regular and flat interlacement of its strands, which cross each other at right angles. However small the original webs may have been, a set of threads—the warp—must in each case have been stretched on some kind

Hosted by Google

of frame. The intersecting threads—the weft —must also have been passed before and behind alternate warp threads in regular sequence. This could only have been done on a loom, however simple, and how simply a loom may be constructed let me exemplify.

Here is an oblong board, two sticks, and a piece of string.

If I wind the string on to the board (Fig. 2), and insert the two sticks between alternate cords at one end, I have made the board and sticks into a simple loom, which is typical of the loom of every country and of all time. It is typical because it has the essential characteristic of all looms, which is the crossing of the threads between the sticks. This cross transforms a collection of any number of separate strings

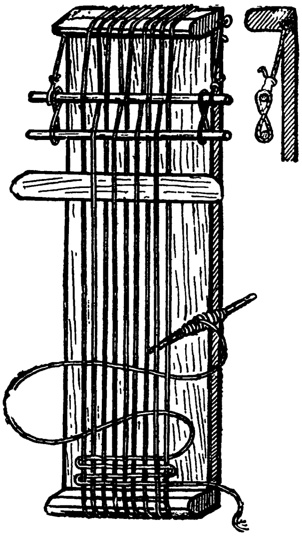

Fig. 2.—Primitive Board Loom and Shed Sticks.

into a well-ordered, weavable warp, which can easily be kept free from entanglement. In fact, without it no weaving could begin, much less be carried on to any length.

There is a roll of East African weaving in the ethnographical gallery of the British Museum. This beautiful strip of cloth is four inches wide, and is a fine specimen of modern primitive weaving. The pretty web, with its delicate pattern of checkers, could quite easily be woven on such a board as this, no other appliances being necessary than the two or three sticks, and a long, thin spindle, or needle, for inserting the weft thread.

Here is a tiny board loom, on which I have had woven a copy of one of the border stripes of the African native web. Fig. 3 (p. 950) is a photograph of it.

You will notice a number of loops hanging loosely to the unwoven threads. I need not refer to them just now, except to say that they are for the purpose of economising time and facilitating the work. Without them, the weaving would take longer, and require a little more attention, but otherwise could be as well done.

If we take a piece of loom-woven coarse canvas and examine it, we shall see clearly the stretched threads of warp and the continuous intersecting thread of weft. If a small fragment of such a piece of textile had been partially burnt, and buried in clay at the bottom of a lake for three thousand years or more, then, discovered by a fortunate archæologist, had been pressed between two glasses for preservation in a museum, it would, I think, when photographed, present very much the appearance of the shred of Lake-dwellers' linen cloth. (Fig. 1.)

I can best illustrate the method of intersecting warp and weft, on my extemporised primitive loom.

[Here the lecturer gave a demonstration of the simplest kind of weaving.]

Before proceeding to inquire into particulars regarding the form of loom used by the Lake-dwellers, it will be advisable to make a digression in order to describe the art of making thread, which naturally precedes the art of weaving.

There is no natural continuous thread except silk, all others being artificial. Silk is unwound from the cocoon of the silkworm in lengths of from five hundred to a thousand yards.

Of this thread primitive man is unaware. But he seems to have an instinct which teaches him that various vegetable and animal fibres, however short they may be, can be twisted together and joined up into threads of any required length and thickness, as well as of great strength. Weaving is well-nigh universal, but, even in the few places where it is unknown, the art of making very perfect thread and netting it into useful fabrics is commonly practised.

The process of making thread may be stated very briefly. It consists of (1) stripping and cleaning the fibres; this is called *skutching*, or ginning. (2) Of loosening and straightening out the cleansed fibres; this is termed *carding*. (3) Of drawing the carded filaments out in an even rove and twisting them together into fine or coarse continuous thread. This final process is called *spinning*.

Hosted by Google

The arts of spinning and weaving have acted and reacted continually on one another. This was notably exemplified during the eighteenth century in this country. At the beginning of the century, weavers were often hindered by having to wait for yarn to weave, the domestic system of spinning by hand not being sufficient to keep pace with the production of cloth. This led to the invention of spinning machinery. By means of this machinery the output of yarn soon became greater than the hand-loom weavers could cope with, although there was still a growing demand for textile fabrics. The application of steam power to the loom and many improvements added to the loom itself increased the speed of weaving, and again equalised the output of the two industries.

There can be no good weaving without good spinning, for good cloth cannot be made of bad thread. Spinning can be done, slowly of course, without any mechanical aid whatever.

Here is a bundle of fibre ready for spinning. It has been simply cleaned and carded. If I draw out a few fibres and, after slightly damping them with clear water, twist them together with my fingers, you will see that they have been converted, simply by the twisting, into a strong thread. Thread thus casually made is naturally coarse and rough, but an expert spinner would make, in the same way, a fine, strong, even thread with very few fibres.

If a small stick, having a hook at one end and a weight at the other, be suspended to the spinning thread, the further even twisting of

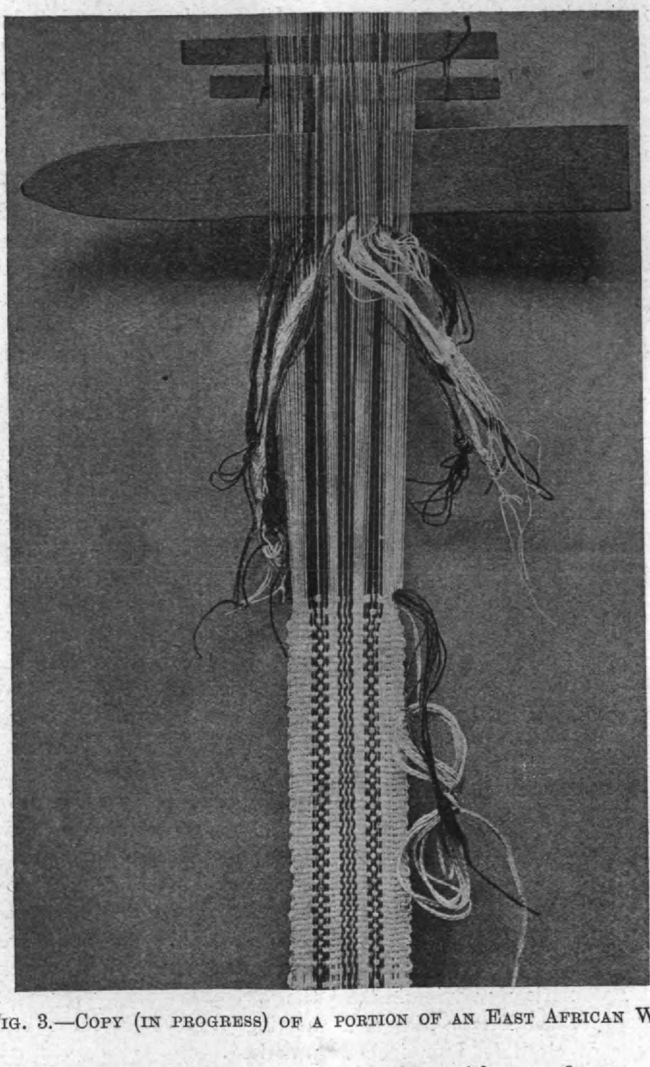

FIG. 3.—COPY (IN PROGRESS) OF A PORTION OF AN EAST AFRICAN WEB.

Hosted by Google

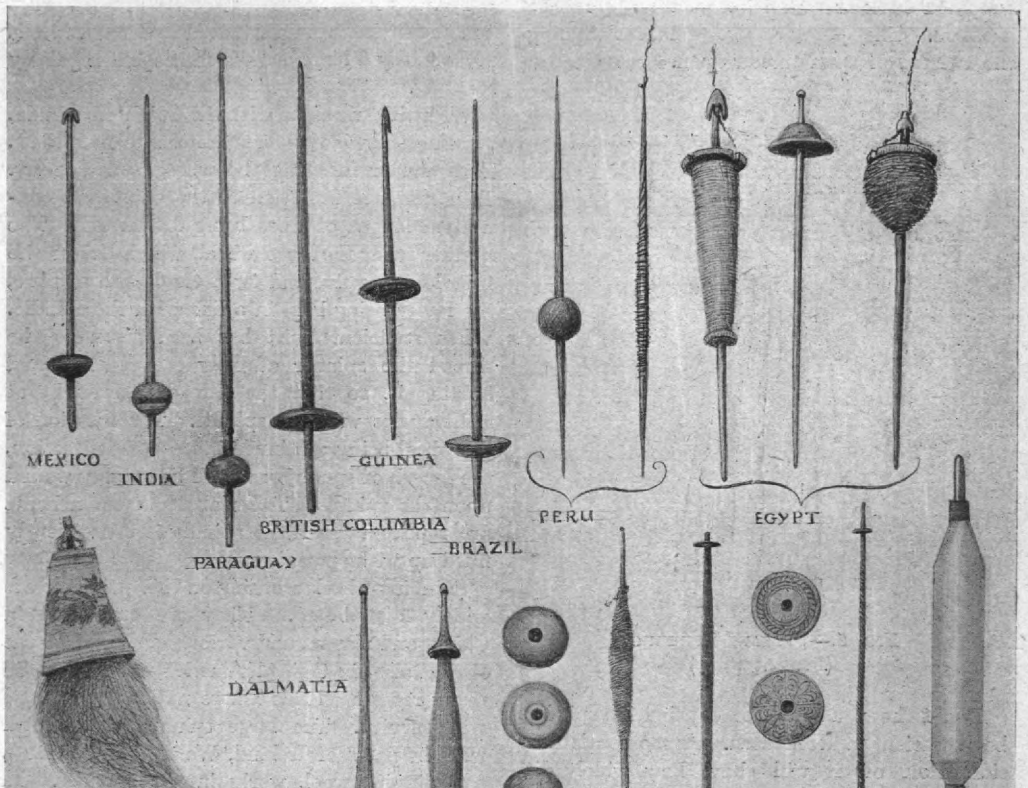

FIG. 4.—A COLLECTION OF PRIMITIVE SPINDLES, A DISTAFF, AND SOME LOOM WEIGHTS FROM VARIOUS COUNTRIES. (Drawn by the Author.)

the yarn will become much easier, because regulated by the continuous revolution of the weighted stick or *spindle*, as such an appliance is called. The spindle is also useful for winding the twisted or spun thread upon.

FIG. 5.—PEASANT SPINNING. (Present time.)

Fig. 4 shows a collection of primitive spindles both ancient and modern. A moment's consideration of it will show how widely distributed and well-nigh universal this simple industrial implement has been. One great advantage the spindle has over all other spinning appliances is that it can be carried about by the spinner without her having to discontinue her work. An ancient story by Herodotus illustrates this point.

King Darius chanced to see a Pæonian woman who was carrying a pitcher on her head, leading a horse and spinning flax. He sent spies after her, and they reported that she filled the pitcher with water, watered the horse, and returned, continuing all the while to spin with her spindle. Darius asked if all the women of Pæonia were so industrious, and being told they were ordered that all the Pæonians, men, women, and children, should be removed from their own country into Persia.

Whether this reward of merit was appreciated by the Pæonians, Herodotus does not say.

There is a painting on a Greek vase of about 500 B.C., which depicts a spinner holding the distaff in a picturesque and graceful, but unusual and, one would think, ineffective way.

Fig. 5 shows the usual method of carrying the distaff, which, it will be seen, leaves both hands of the spinner free for drawing out the fibre and twisting the spindle.

Fig. 6 is from Roth's "Natives of Sarawak," and shows the spindle attached to a small wheel, actuated by a large one which keeps it regularly rotating.

With this wheel, as with the weighted spindle, twisting and winding on are alternate operations. The manner of using the wheel is as follows. The thread is first tied to the spindle, a convenient length of fibre being drawn out. The spinner turns the large wheel, which causes the spindle to revolve and twist the length of fibre, the latter being held in a line with the spindle. When sufficient twist has been given to the thread the spinner adroitly moves the hand holding it, so that the thread is brought at right angles with the spindle. The rotation of the wheel being continued in the same direction, the length of spun thread will be quickly wound upon the spindle. These alternate movements are repeated until the spindle is conveniently filled up with spun thread.

Spinning-wheels working on this principle are widely distributed. They are still used in China and Japan, and various countries of the East; also in Central America, as well as in many remote islands where native textile arts still survive. The large spinning-wheel, still used in parts of Ireland, Wales, and Scotland, for spinning wool, works in this manner. In Scotland it is called the *muckle* wheel.

Spinning with a wheel may have been practised in Europe in ancient times, but there is no

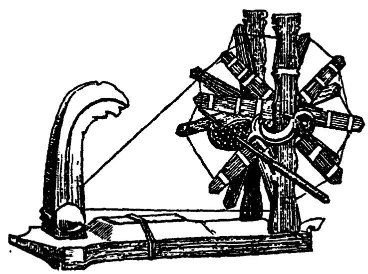

FIG. 6.—NATIVE SPINNING-WHEEL. (From Sarawak.)

evidence to prove it. The thread is the same whether spun with or without the help of a wheel. The best and finest workable thread ever produced has been spun in India by means of the spindle, at Dacca, where the famous Dacca muslins are still woven by hand from hand-spun thread.

The well-known ordinary spinning-wheel, sometimes called the Saxony, or German wheel, has

Hosted by Google

been in use since the sixteenth century. It has an ingenious arrangement, by means of which the two operations of twisting the thread and winding it are done simultaneously. As, however, it carries the art of spinning beyond the primitive stage, I must leave its description to my next lecture.

After this rather lengthy but necessary digression, we may resume the inquiry as to the loom in its ancient and primitive form.

The presence amongst the textile relics of the Lake-dwellers of a few circular and conical shaped objects of stone and earthenware, gives a clue to the form of loom on which the prehistoric webs were woven. Such objects, pierced with holes, and sometimes elaborately ornamented, are found in excavations all over Europe. These objects are precisely like the weights which the Greeks and Romans and other ancient European peoples used for the purpose of stretching the threads of warp in their peculiarly-constructed upright looms (see Fig. 4).

Seeing, then, that similar objects to these are found amongst the Lake-dwellers' relics, it is reasonable to conclude that they were used for the same purpose, and that the form of the prehistoric loom was the same as that of the looms of a later period of which we have representations.

Amongst the vase paintings of ancient Greece only four representations of the loom are found. Two of these are rough though expressive caricatures painted on Bœotian pottery. The loom in each of these sketches is very definite,

FIG. 7.—GREEK LOOM.
(From Bœotian Vase Painting. 500 B.C.)

and, as far as it goes, evidently correct in detail. One of these painted pots is in the Bodleian Museum at Oxford, and the other, of which I have a photograph, is in the British Museum.

The subject of the painting is Kirke presenting the noxious potion to Odysseus. The loom is simply a pair of upright posts with a cross-piece joining them together at the top. Beneath the cross-piece is a roller, or beam, on which the cloth is wound as it is woven. The unwoven warp is seen hanging nearly to the ground, where it appears to terminate in two rows of circular weights. These weights keep the warp threads taut, and two sticks

FIG. 8.—PENELOPE'S LOOM.
(From Greek Vase Painting. 500 B.C.)

intersect the threads in order to retain the cross between them alternately, so keeping the warp from entanglement and preserving an opening for the passing and interlacing of the weft. In the Oxford vase, the weft is shown wound on a kind of mesh such as is used in the making of nets.

Fig. 8 is copied from a beautiful Greek vase painting. Its date is about 500 B.C. This is a much more careful and elaborate painting, but it tells little more about the loom and its arrangement. The loom is of the same simple construction, but all the parts are more carefully drawn and the pattern of the web—a highly ornamental one—is distinctly shown. There are also pegs on the top cross-piece of the loom, on which spare balls of different coloured weft are kept handy for use. Spare warp was also probably hung from them at the back of the loom.

The weights at the bottom of the loom in this case are of a conical shape, very much like those found in Switzerland. There is also, at the back of the loom, another stick or beam, which is, I believe, for the purpose of holding

Hosted by Google

the length of unwoven warp before it passes through the holes in the weights at the bottom of the loom. The loose back threads are not shown in the painting, but the roll of cloth upon the beam indicates that more than a loom's length of warp is being manipulated. Probably the artist shirked the difficulty of representing these back threads, and so made the front ones appear to terminate at the weights.

This painting is particularly interesting, because it shows unmistakably that the elaborate pattern webs, which the classic poets so often referred to, were woven on the simplest of

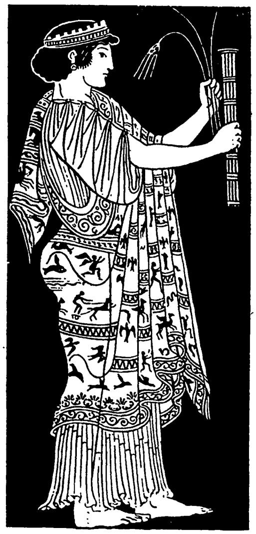

FIG. 9.—PROCESSIONAL FIGURE.
(From a Greek Vase Painting. 500 B.C.)

looms by skilful handicraft, not by means of complicated machinery, as some have supposed. In proof of this, if you will notice the border of grotesque creatures which Penelope has just woven, you will recognise its likeness to the pattern on the robe of a processional figure, copied from another vase painting of the same period, which is the subject of Fig. 9.

On a tiny vase in the British Museum there is a slight sketch of a lady weaving on a small frame, which she holds on her lap.* In this case the strings of warp are merely stretched on the frame, and there are no loom weights. There is, however, a peculiarity in the method of working depicted which unmistakably links this diminutive loom with those of Kirke and Penelope, as we shall presently see.

* Gallery of Greek and Roman Life B.M.

Olaf Olafsen, in a work on Iceland, published in Amsterdam in 1780, gives an illustration and account of a traditional loom still used, at his time, in that country. There are two or three more or less imperfect copies of Olafsen's drawing in English books, which show the striking points of resemblance this loom bears to the looms of ancient Greece.*

Looms constructed in the manner which required the kind of weights found in the Lake Dwellings, those depicted in use on the classic vases, and the traditional looms of the north of Europe, all agree in requiring a method of weaving which differs from that of all other looms the world over. This peculiarity was noticed by Herodotus, who visited Egypt about 400 B.C., and recorded his impressions. Speaking of the Egyptians, who appeared to him to do everything in a contrary manner, he says: "Other nations"—meaning, of course, Europeans—"throw the wool *upwards* in weaving, the Egyptians *downwards.*"

Now, if you will glance again at Figs. 7 and 8, after you have noted the point on the Icelandic one, you will see that the webs on these looms are all being woven from the top. This necessitates beating the weft *upwards*, as the Greek historian says, and also winding the cloth upon the top roller. In fact, the method of stretching the warp by the hanging weights, and the necessary relative position of the cross-sticks, make it impossible to weave in any other way.

The Greek lady weaving on a small frame I referred to is also shown *commencing at the top*, although in her case, the warp being stretched upon a frame, it is not necessary to weave in what we should consider an awkward way; her doing so, however, shows that it was the custom to which she was used.

The people of ancient Egypt did a large export trade with Europe, and distant parts of Africa and Arabia, in manufactured linen, the fine linen of Egypt being unrivalled in the ancient world for evenness and fineness of texture.

Owing, no doubt, to the dryness of the climate of Egypt, and the peculiar funeral customs of the Egyptians, many specimens of ancient Egyptian textiles have been preserved. Linen cloth, which was woven four or five thousand years ago or even more, may still be seen and handled, being as perfect as when it was newly cut out of the loom by the industrious Egyptian weaver.

* One of these is an illustration to the article "Tela," in Smith's "Dictionary of Greek and Roman Antiquities."

Hosted by Google

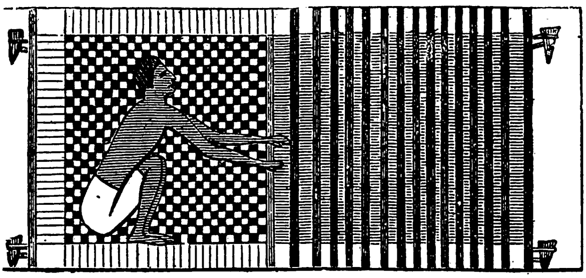

FIG. 10.—EGYPTIAN LOOM AND WEAVER.

In the British and other museums many examples of such Egyptian linen textiles may be seen. These linen cloths were unwrapped from mummies whose funerals took place under the various dynasties. As to the looms on which these textiles were woven, the few representations of them which exist show that they were constructed on a different plan from those of Europe, and bear out the statement of Herodotus that the Egyptians beat the weft downwards instead of upwards when weaving.

Only three pictures of ancient Egyptian looms are known to exist, and there seem to be no traces or fragments whatever of the looms themselves.

The drawings of Egyptian looms (Figs. 10, 11, and 12) were made from wall paintings at Bene Hasan and Thebes in Upper Egypt. Fig. 10 is rather a puzzling one, because the artist has combined a bird's-eye view of the loom with a side elevation of the weaver. The warp, which is a short one, is simply stretched upon the ground. There are no rollers or loom frame of any kind. The weaver is making a carpet or mat, it may be of rushes or grass. The only distinct facts to be gathered from this drawing are that the weft is being beaten down and the web is growing upwards; also that the warp is fixed at both top and bottom.

In Fig. 11 two weavers work at a small upright loom. The weaver to the right is inserting a stick, with a hook at the end, into the warp. This hooked stick has been the subject of much discussion, but I believe it is really a spindle with the weft wound on it, the artist not being able or not having troubled to indicate the thread. Possibly he was an ancient post impressionist, and only represented symbols and souls of things, not their actual appearance or sordid detail.

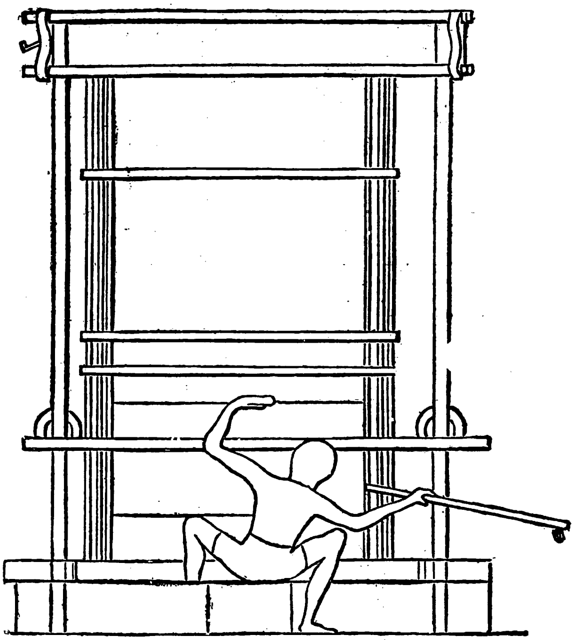

FIG. 12.—EGYPTIAN LOOM FOR LINEN WEAVING.

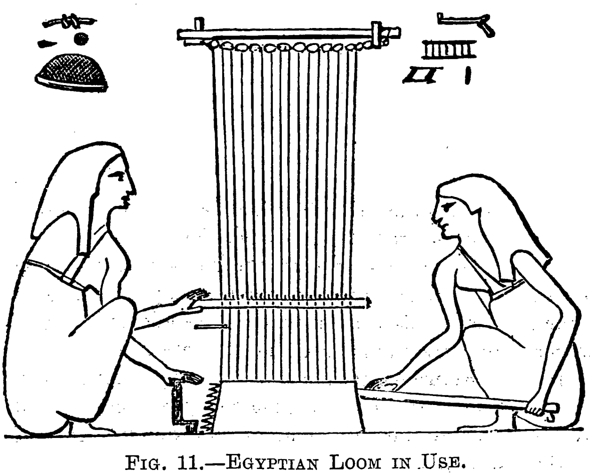

FIG. 11.—EGYPTIAN LOOM IN USE.

The weaver on the left is evidently preparing to beat the weft together with the comb which is ready to descend upon it as soon as it is inserted. Here, again, the warp is fastened at the top and bottom of the loom, and the web is growing upwards. As the loom has no rollers either at the top or bottom, only a loom's length of material can be woven on it.

Fig. 12 is a much more effective-looking loom than either of the foregoing, although there are many puzzling

points about it. It has loom posts, and is evidently a solid structure. There are no rollers definitely shown, but they may well be there. The arrangement of sticks at the top may be intended to represent a skeleton

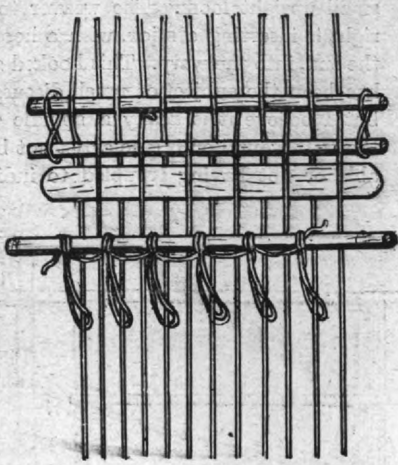

FIG. 13.—HOOPS AND HEDDLE ROD.

roller, and the bottom one on which the cloth is wound as it is made may be hidden by the bench on which the very active weaver, wielding the hooked stick, is at work. The cross-sticks

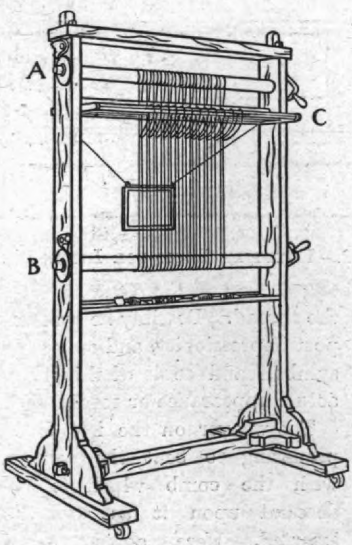

FIG. 14.—TAPESTRY LOOM.

are shown, but their purpose could never be detected from the picture. There is not much indication, only a line, as to which is woven web and which unwoven warp. I imagine the line just above the weaver's knee is that of the already woven portion, and that all above is unwoven warp. Also that the line by the weaver's left hand indicates where he is picking up alternate threads to make an opening for the weft which is wound upon the hooked stick or spindle.

Anyhow, we have here the warp stretched between the top and bottom bars, or probably rollers, of an upright loom of solid construction at which the weaver is at work in such a position that he must be beating the weft downwards, and the web be growing upwards.

Fastening the warp at both ends to rollers and weaving upwards are without doubt great advances on the ancient European methods of procedure. A further advance is the invention of what is now called the heddle rod. There is no direct evidence of this valuable

FIG. 15.—EGYPTIAN TAPESTRY.
(Cairo Museum. 2000 B.C.)

addition to the loom either in ancient Europe or in Egypt, but it is difficult to believe that the extremely fine wide linen of Egypt could have been woven, to the extent it was, without this simple and obvious appliance. Some of the finest Egyptian webs have as many as 150 threads of warp to every inch of their width, and it seems incredible that this multitude of fine threads could have been profitably manipulated with the fingers only.

It is possible that the bar across the loom (Fig. 12), on which the weaver is apparently only resting his arm, may be a heddle rod. This important appliance I must now explain.

Returning for a moment to Fig. 3, let me call your attention to the loose loops which I pointed out as time economisers, but did not further describe.

Hosted by Google

FIG. 16.—GREEK TAPESTRY. (500 B.C.)

FIG. 17.—EGYPTO-ROMAN TAPESTRY PANEL. (Victoria and Albert Museum.)

These loose loops are attached one to each thread of the warp, which is at the back of the lower cross-stick. The cross-stick makes one shed, or opening, for the weft. The loops, on being pulled forward, bring the back threads to the front and so make the second or alternate opening.

You will see this at once if I add loops to my simple loom and insert a rod to enable me to raise them all together.

[Here the lecturer demonstrated the use of the heddle rod (Fig. 13).]

As an appliance for two important branches of textile work—tapestry weaving and the weaving of hand-knotted pile carpets—the loom, at the point we have now reached, seems to be capable of no further development.

This loom, simple as it is, cannot be improved in its mechanism, except perhaps in some unimportant details, for the use of the artist weaver to work out his free designs upon.

All the gorgeous and more or less elaborately ornamented carpets of the East, as well as the exquisitely-wrought tapestries of the West, from the most ancient times to our own, have been woven on looms of no more complicated construction than this. Added mechanical contrivances limit the scope of the craftsman. Freedom of design is trammelled in proportion to the facilities invented for the automatic repetition of pattern in the loom.

FIG. 18.—THE PERSIAN COPE. (Victoria and Albert Museum.)

Fig. 14 is a design for a small tapestry loom from Mrs. Christie's "Handbook of Embroidery and Tapestry Weaving."*

The six illustrations, with which I conclude this lecture, are taken from masterpieces of weaving made, on looms of no more elaborate construction than Fig. 14, at different periods by equally skilled craftsmen in various parts of the world.

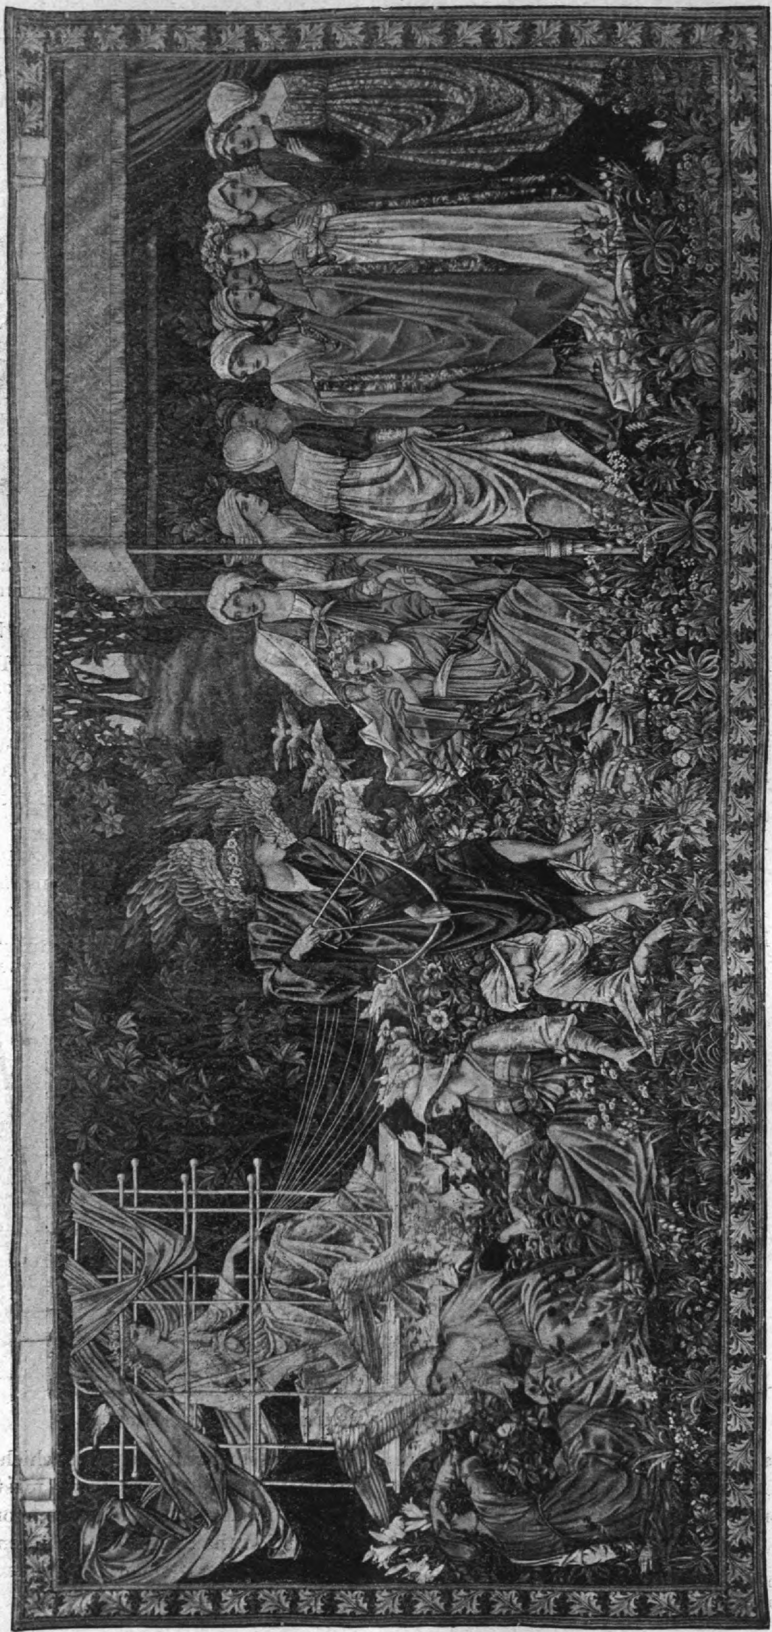

FIG. 20.—"THE PASSING OF VENUS." MORRIS TAPESTRY. (Designed by the late Sir E. Burne-Jones.)

Hosted by Google

Fig. 15 is the most ancient piece of ornamental tapestry weaving known to exist. It is extremely fine in texture, the whole piece being only 4 ins. by $1\frac{1}{4}$ ins. in size. It formed part of the robe of Amenhilep III., who reigned in Egypt 2000 B.C. The original is in the Cairo Museum.

FIG. 19.—PORTION OF A BRUSSELS TAPESTRY. (Victoria and Albert Museum.)

Fig. 16 is a piece of Greek tapestry of about 500 B.C. It was discovered in the relics of a Greek colony in the Crimea. The original is in the Hermitage Museum, St. Petersburg.

Fig. 17 is a fine piece of Egypto-Roman tapestry, woven of coloured silk unwoven from Chinese webs. The actual size of the little panel is 4 ins. by 4 ins. It formed part of a child's tunic in the fifth century A.D.

Fig. 18 is a piece of Persian weaving of the sixteenth century. It may have been woven in Venice by Persian weavers. It is an exquisite example of hand-knotted velvet pile, there being as many as 400 knots to an inch. The colour and ornamentation are superb. It is one of the choicest treasures of the Victoria and Albert Museum collection, and is called the Persian cope.

The same museum possesses a set of Brussels tapestry of the sixteenth century. The figures are life-size, and are splendidly wrought. Fig. 19 represents a portion of one of the panels.

The subject of Fig. 20 is a modern tapestry by Morris & Co. The design, "The Passing of Venus," was made by the late Sir E. Burne-Jones. The tapestry took seven years to produce, and, being sent to the recent Brussels Exhibition, was destroyed in the disastrous fire which took place there, together with many other art treasures.

FIG. 21.—TAPESTRY WEAVING IN THE MERTON ABBEY FACTORY OF MESSRS. MORRIS & CO.

All these examples of tapestry weaving were made on such looms as Fig. 14, and are really mosaics of plain weaving with a loose weft.

Fig. 21 is a photograph of the tapestry-weaving workshop of Messrs. Morris & Co., at Merton Abbey.

Next week I shall deal with spinning machines, and the development of the loom for automatic pattern weaving.

HAIL INSURANCE IN AUSTRIA.*

The Austrian Minister of Home Affairs has recently published three reports, with intervals of only a few months between each, upon private enterprises that during the years 1907, 1908, and 1909 have transacted various branches of insurance business in the kingdoms and countries represented in the Council of the Empire. In the June number of the *Bulletin of Economic and Social Intelligence* of the International Institute of Agriculture, the most important data contained in these reports relative to one of the most useful branches of agricultural insurance, that is hail insurance, are reproduced and commented upon.

The business of hail insurance is transacted in

* Summarised from the *Bulletin of Economic and Social Intelligence* of the International Institute of Agriculture, Rome. Year III., No. 6. June, 1912.

Hosted by Google

Austria only by national and Hungarian institutes, seventeen in all. Taking account of their form of organisation, they may be divided into four national societies limited by shares, ten mutual institutes (seven large mutual institutes and three local societies), and three Hungarian societies limited by shares. The extension of the operations of the insurance institutes working in the territory of the Empire is examined in the above-mentioned study from three points of view: (a) the number of policies and the amounts insured; (b) the amount of premiums collected; (c) the amount of claims paid. From the statistical tables we see that hail insurance tends to spread more and more among the farmers of the Empire, although when we consider a long series of years we see that the increases in the number of policies and in the amount insured are somewhat inconstant and irregular. This depends on the irregularity of the risk of hail itself; sometimes long periods pass without any devastating hailstorm to be reported, and the farmers, trusting in the continuance of this, are indisposed to insure.

The country in which insurance institutes are most numerous is Bohemia, where there are fifteen societies working (exclusive of three local societies). Next comes Moravia with twelve societies; on the other hand, there is only one society working in the Littoral and two in Carinthia. In Dalmatia and in Tyrol, including Vorarlberg, no insurance business was done.

In the case of every region of the Empire data are given as to the amount insured, the average amount insured for each contract, and the amount of the average premium as percentage of the amount insured. Thus, examining the first group of data, the reader may form an idea on the development of insurance in the separate territories; the data as to the average sum per policy are of considerable interest as indications of the distribution of large and small property; finally, the amount of the average premium shows how the risk of damage from hail is generally estimated by the insurance societies in the various regions of the Empire.

Thus, for example, the average value insured per policy in six Austrian mutual institutes varies between 1,266 and 2,685 crowns, while, on the other hand, the average amount insured in the mutual institute of Cracow is 7,663 crowns. This appreciable difference is explained by the economic and social conditions of Galicia; the small landowners insure to a relatively smaller degree in this country than in other territories of the Empire.

In the statistical tables showing the premiums collected in recent years, we see that these premiums tend to increase, probably in consequence of the heavy hailstorms, that have lately been more frequent and more violent.

We observe, finally, that also in Austria the societies limited by shares are the institutes that extend their business most widely; it is enough to say that of four such societies, two were working in eleven regions and one in ten, while of the seven mutual societies only one was working in six regions, four limited their operations to three regions, one to two and one to a single region. And while all the societies limited by shares extend their operations beyond the limits of the Empire (all of them work in the countries under the Hungarian Crown and one also in Italy), on the other hand, the direct insurance business of the mutual institutes is limited to the regions of the Empire.

Generally, however, there is useful competition between the two forms of organisations.

MAP OF THE WORLD.*

I would like to allude to a very important geographical undertaking which has made considerable progress during the past year. This is the production of the international Map of the World on the scale of $\frac{1}{1000000}$, a project which has been under the consideration of the leading geographers of the important countries for more than twenty years, since it was first proposed at the International Geographical Congress held at Berne in 1891. The question was discussed at succeeding Geographical Congresses, but did not take definite shape until the meeting held at Geneva in 1908, when a series of resolutions dealing with the subject were drawn up by a committee composed of distinguished men of many nations, which was appointed to formulate rules for the production of the maps, so as to ensure that they should be prepared upon a uniform system.

These resolutions were approved at a general meeting of the Geneva Congress, and were forwarded by the Swiss Government to the British Government for consideration, whereupon the latter issued invitations to the Governments of Austria-Hungary, France, Germany, Japan, Russia, Italy, Spain, and the United States of North America, asking them to nominate delegates to act as the members of an International Committee to meet in London and debate the question. This committee assembled at the Foreign Office in November 1909, and Colonel S. C. N. Grant, C.M.G., then Director-General of the British Ordnance Survey, was appointed President. The proceedings were opened by the Under-Secretary of State for Foreign Affairs, Sir Charles Hardinge, G.C.M.G., now Lord Hardinge, who, in his address, referred to the progress that had already been made with regard to the international map, and expressed the hope, on behalf of the British Government, that the great undertaking might be brought to a satisfactory conclusion.

The main business before the committee was to settle on the mode of execution of the map, especially as regards the size of the sheets, so as to

* Extracted from the Presidential Address to the Geographical Section of the British Association, by Colonel Sir C. M. Watson, K.C.M.G., C.B.

Hosted by Google

ensure that adjacent sheets, published by different countries, should fit together; and also to settle upon the symbols, printing, and conventional signs to be used, in order that these should be uniform throughout. A series of resolutions, embodying the decisions arrived at concerning these various points, was approved and drawn up in English, French, and German, the first of these languages being taken as the authoritative text. As the map was to embrace the whole surface of the globe, the method of projection to be adopted was, of course, a very important consideration, and, after due deliberation, it was decided that a modified polyconic projection, with the meridians shown as straight lines, and with each sheet plotted independently on its central meridian, would prove the most satisfactory.

The surface of the sphere was divided into zones, each containing four degrees of latitude, commencing at the equator, and extending to 88° North and 88° South latitude. There were thus twenty-four zones on each side of the equator, and these were distinguished by the letters A to V north, and A to V south. This fixed the height of each sheet. For the width of the sheets, the surface of the sphere was divided into sixty segments, each containing six degrees of longitude, and numbered consecutively from one to sixty, commencing at longitude 180°. This arrangement made each sheet contain six degrees of longitude by four degrees of latitude; but as the width of the sheets diminished as they approached the poles, it was decided that, beyond 60° North, or 60° South, two or more sheets could be combined. Each sheet could thus be given a clear identification number defining its position on the surface of the globe, without it being necessary to mention the country included in it, or the latitude and longitude. For example, the sheet containing the central part of England is called North, N. 30.

In order to ensure that the execution of all the maps should be identical, a scheme of lettering and of conventional topographical signs was drawn up and attached to the resolutions; and it was decided that a scale of kilometres should be shown on each sheet, and also a scale of the national measure of length of the country concerned. As regards the representations of altitude, it was arranged that contours should be shown at vertical intervals of a hundred metres, or at smaller intervals in the case of very flat, and larger in the case of steep ground, the height being measured from mean sea-level, as determined in the case of each country; while the levels of the surface of the country were to be indicated by a scale of colour tints, the colours being green from 0 to 300 metres, brown from 300 to 2,500 metres, and purple above 2,500 metres. In the same manner the depths of the ocean and of large lakes were to be indicated by varying tints of blue, so as to show intervals of 100 metres. In order to ensure uniformity in the scale of colours to be used, a copy of it, as approved by the committee, was included in the plate of topographical symbols.

The whole scheme was thoroughly well worked out, and great credit is due to the members of the International Committee for the manner in which they carried out their difficult task. Since the meeting of the committee in 1909 the preparation of the sheets in accordance with the principles decided upon, has been taken in hand in several countries, and a number of these have been issued which give a good idea of what this great map—the largest ever contemplated—will be like. These sheets deserve to be carefully studied, and will doubtless be the subject of considerable criticism, as there are several points which seem worthy of examination.

CHINESE BLACKWOOD FURNITURE.

A characteristic product of China known all the world over, and admired in varying degrees by foreigners generally, is Chinese blackwood furniture, including cabinets, chairs, stools, pedestals, centre and side tables, frames, and articles for the drawing-room, elaborately carved and decorated, and manufactured or supposed to be made from a blackwood. This furniture, if real in all respects, is produced from various dark woods, generally from *Dalbergia lotifolia*, or hard, heavy, close-grained, dark red wood, known to the Chinese as "ka-hee" or "furniture wood," or sometimes as "sun-gee" or "dark red wood." When exposed to the air for a long time this wood turns dark and eventually becomes black, with more or less red streaks in the grain corresponding to the amount of resinous or other colouring matter in the grain. Originally the Chinese used this wood for their own fine furniture and for wood bases, or frames for porcelains, jade carvings, or other ornaments for display in drawing-rooms. Chinese furniture ordinarily is quite plain, generally constructed in long curves or rounded corners, straight backs to the chairs, settees with straight backs, often set with porcelain or marble panels, and similar pieces, while bases for porcelain or other similar work were often beautifully carved. With the advent of foreigners in South China, however, there came a demand for a combination of furniture more or less on the Chinese model, which was carved instead of plain. The Chinese manufacturers eventually designed furniture somewhat on foreign models with the popular elaborate carved ornamentation, the local demand for which spread into a world-wide trade. According to the American Consul-General in Hong-Kong, the actual volume of this trade is not large, the United States probably taking more of it than any other nation. Formerly most of this furniture was made in Canton, which still annually sends £9,000 worth, practically all to Hong-Kong, besides a considerable quantity shipped abroad as household furniture. In Canton, a district practically given over to the manufacture of such furniture is a point of interest for tourists. Of late years these factories have sprung up in Hong-Kong, where most of the product is actually

Hosted by Google

sold to users, and there are now eight such establishments. A few years ago there was a good deal of fraud in the business, and soft light woods stained black were used, just as most of the so-called cherrywood furniture in Japan is now soft white wood stained cherry before finishing. The use of poor wood so injured the trade that the Chinese guild concerned decided to use only the real blackwood, and this in Hong-Kong is characteristic of the trade, though, of course, there is still need to guard against inferior woods. Practically all the hard wood furniture is hand-made. Furniture is planned in parts, which generally dovetail together in order to eliminate screws or nails, and the various parts are shaped for the carver. The latter sits on the earth floor and works with various knives, chisels, and other tools of native workmanship, but with no other bench than that afforded by his legs, toes, and the earth floor, or in exceptional cases, a log combination of seat and bench. Workmen in these shops are practically bred to the business. An apprentice serves three years with no other pay than his rice. He then earns about one sovereign per month. An experienced carver will ordinarily receive two pounds per month. When carved the article is usually stained a uniform black by an alum preparation, then waxed with a preparation of wood oil and blacking, and polished, or sometimes finished with a special preparation of Ningpo varnish. Foreign oils and varnish are sometimes used for special purposes, but as a rule only native materials are employed. The popularity of Chinese blackwood furniture seems on the whole to be increasing, and a strong demand is growing for furniture manufactured from this wood on plainer lines, and to some extent for settees and chairs in Chinese styles.

ENGINEERING NOTES.

Centenary of Krupp's.—The centenary, or rather the first year of the second century, of the well-known steel works in Germany has just been celebrated with great pomp and circumstance. We are accustomed to regard the German establishments of which Krupp's stands first as keen modern rivals of a large number of our engineering industries; but with Krupp's this began so far back as November 1811, when Friedrich Krupp opened a small manufactory in Altenessen, not only to compete with English supplies of cast steel, but to supply the place of importations from Great Britain, which had been blocked by the strategy of Napoleon. It was a very small factory and was worked by water-power, and, to show the great advance that had been made between then and now, we find that the population of the town at that time was 4,000, and now, through the influence of the Krupp works, it amounts to 300,000. At first, however, there was a great struggle, and Friedrich Krupp died in 1826 broken-hearted by failure. It was his son, Alfred, who was born in 1812 and lived till 1887, who created the business that now spreads over the whole world, and he might be rightly called "the Father of the Steel Industry." There were only four men employed at the works when the elder Krupp died, whereas in 1873 the number had reached 16,000, and when Alfred died there were 20,000. Now, in 1912, there are 36,000 men at the steel works alone, beside 32,000 in the employment of the firm on works in connection with the business at Essen and elsewhere. At the London Exhibition of 1851 the British manufacturers were astonished to see exhibited by Krupp's a steel block of no less than 4,500 lbs. weight. This was three years after the works had been sold by the family to Alfred Krupp for £5,000. Up to the sixties, purely cast steel products were the business of the works; but since then nearly every branch of engineering material has been turned out, more especially rifle barrels and cast-steel guns, which had begun to supersede bronze. In 1867, he introduced hooped and jacketed guns, and two years later gun-mountings. In the early eighties the business was turned into a company. Armour plating for ships and steel rails, which had begun to displace iron, gave the firm further opportunities; so that now the works which had been managed by Friedrich Alfred Krupp, Alfred's son, who died in 1902, comprise, besides the Essen establishment, three collieries, many mines, a wharf at Rotterdam, and the Germania shipyards at Kiel. At present the head of the firm is the Baroness Krupp von Bohlen-Holbach, the great-granddaughter of Friedrich, who is married to the Baron of that name, and was authorised to continue the family name in her new title.

Electric Furnace for Non-ferrous Metals.—The Pittsburg Electric Furnace Company, of Pittsburg, Pennsylvania, have recently installed furnaces for melting brass, drosses, scrap metals, and other non-ferrous metals and alloys. The inventor of the process used at Pittsburg is R. T. Wile, the manager of the works. The current of electricity used may be either direct or alternate, and the furnaces stationary or tilting. The stationary furnaces have up to 20 tons capacity, and the tilting ones vary up to 1,000 lbs. a charge. A furnace melting a charge of 200 lbs. of brass consumes 22 kilowatts at a hundred volts, 500 lbs. require 32 kilowatts, and 1,000 lbs. 68 kilowatts.

Internal-combustion Locomotives. — Necessity is the mother of numerous children besides invention, one being the adaption of invention. The Trans-Australian Railway, the construction of which is now in hand, will run through 1,060 miles of the Commonwealth, most of which is practically waterless country, for the little rain that falls is lost by percolation through the limestone formation of which the country is composed. Owing to this fact, and that the steam engine was the only method of traction in view when the estimates were made, no less a sum than £609,000 was

Hosted by Google

estimated for providing water for the locomotives. The internal-combustion locomotive has, therefore, been thought of as a means of getting over the difficulty; but there has been no example so far of this machine on long-distance lines. On the Great Central Railway there has been recently put into service a Westinghouse internal-combustion coach, having a 90 horse-power six-cylinder petrol engine, driving a 55-kw. dynamo, which in turn supplies power to two electric motors. This vehicle is stated to be capable of a speed of forty miles an hour on the level, to weigh twenty-five tons, and to have seating capacity for fifty passengers. Petrol-electric coaches of this character are said to be running on the Hungarian railways at half the running cost of steam motor coaches, and there have been numerous gasoline motor coaches for a considerable time in service in America. Internal-combustion engines have also been tried on the South African railways. It may be explained to readers who are not familiar with the difference between steam locomotives and those of which we are speaking, that instead of steam from the boiler being forced into the cylinders, a mixture of air and gasoline vapour is sucked into the cylinders by the piston. It is true the power cannot be efficiently obtained until this mixture is, to a greater or less degree, compressed, which is done on the up-stroke of the piston. Then by a simple, small, insignificant electric spark this compressed mixture is immediately transformed into a pressure and power-giving medium. There is an advantage that in the steam locomotive three or four pounds of fuel per hour per horse-power is used, whereas in the other engine one pound of oil is only required for the same duty. More experience is yet required with regard to control, reversal, and repairs; but these are comparatively small matters in the case of a desert railway, in which the water question is paramount; so that it may come to pass that the initiation of internal combustion traction for long-distance main lines may take place in the Antipodes, and serve us as a warning or example, as the case may be. In a recent number of the engineering supplement of the *Times*, attention was drawn to the possibilities of the "Diesel" oil locomotive. In this it was stated that so far it had not been used for locomotive purposes on road or rail, but, as had been announced a few weeks ago, Dr. Diesel is at work on a 1,000 to 1,200 h.p. Diesel locomotive. Steam locomotives have, of course, been made of much larger sizes, and this engine will not, therefore, improve on recent locomotive practice in this respect, but it may be expected to show very large economies in fuel consumption. The engine referred to is of the two-stroke cycle, four-cylinder type, having its cylinders arranged in pairs, at an angle of 90°. The engine is directly geared to the driving wheels, and does not transform its power electrically. An auxiliary engine drives the air-pumps for giving increased torque when starting, or when climbing a grade. The whole is expected to weigh about 85 tons. It will be seen that this locomotive gives the most direct form of challenge to the steam locomotive.

The Engineering Trades.—Practically all the engineering trades are under almost boom conditions, with the exception of that of steam-engine manufacture. Locomotive builders, hitherto lagging behind in their orders, are improving in this respect; this, in some instances, being due to Australian pressure, the local firms being unequal to the demand.

OBITUARY.

James Pitkin.—Mr. James Pitkin, who had been a member of the Society since 1871, died on August 20th at the age of eighty-six. Mr. Pitkin had carried on business for nearly sixty years past as a scientific instrument manufacturer, and as a maker of meteorological instruments he had acquired a considerable reputation. He is credited with having been the inventor of the pocket aneroid, that is to say, with having made the first aneroid of a portable character. He was also one of the first—if not the first—to construct a satisfactory portable electric lamp, for it was not long after the storage battery was perfected that he succeeded in producing a lamp which could be carried about, and was fitted with a compact and convenient battery. In it he used a perforated screen of thin vulcanite for the purpose of separating the leaden plates. This lamp attracted a good deal of attention at the time, and a large number of the lamps was sold. Mr. Pitkin was well known to many scientific men, who appreciated the excellence of his work, and was much liked by those with whom he came in contact.

GENERAL NOTES.

Olive - preserving in Spain.—Among the various kinds of olives grown in Spain, the variety known as the "Sevillanès" is particularly in demand for the South American market as well as for export to the United States. These olives, which often weigh as much as 15 grams (nearly ½ oz.) each, are preserved chiefly in Seville. After being steeped for a few days in an alkaline lye (prepared from wood ashes) in order to remove the bitter taste, the fruit is well washed in running water. The olives are then placed in large tubs filled with weak brine. Here they are allowed to remain for a few weeks, during which time a slight fermentation, indicated by the scum which forms on the surface of the liquid, sets up. The fruit is then taken out, sorted and put up dry, in jars, bottles, small barrels, or even packed in wooden boxes. The preservation of the olives is due to the fermentation, as is the case with the chopped cabbage of *Sauerkraut*. In Algeria, olives are

Hosted by Google

sometimes treated in a somewhat similar fashion, and after being taken from the brine and dried they are rubbed over with olive oil, and put up in glass jars or wide-mouthed bottles which are closed hermetically. The olives treated in this way are richer in oil and darker in colour than those of Seville, and are much appreciated in France.

THE SHIPPING TRADE IN HOLLAND.—The shipping trade generally appears to have been good last year in Holland. During 1911, 2,358 vessels, representing a tonnage of three and a half millions, entered the port of Amsterdam. At Rotterdam the entries during the same period were 9,425 vessels, with a tonnage of 18 millions. The trade of Holland with her possessions in the East Indies is very considerable, and the Dutch flag, which in 1910 occupied the fourth place in the traffic through the Suez Canal, last year was the third in importance amongst the ships of other nationality. Shipbuilding was also very active in Holland last year. No fewer than 1,100 new vessels, with a registered gross tonnage of 223,180 tons, were launched during the year, 659 of which were less than 100 tons in burden. This year it is estimated that the output will be still greater, as the yards throughout the country are working to their full capacity, and many orders have been placed in the United Kingdom. Last year Holland imported to the value of £272,103,309 sterling, and exported to the value of £219,363,222, as compared with £261,450,052 imports and 204,562,613 exports in 1910.

DECREASE OF POPULATION IN FRANCE.—The decrease of the population in France is a fact which is causing considerable anxiety at the present time to statesmen and economists in that country. The number of births, which has fallen off from upwards of a million every year at the time of the Franco-German War, forty years ago, to 742,114 in 1911, as compared with the number of deaths, which was 776,983 during the same period, shows a loss of 34,869 inhabitants during the year. Whilst in other European countries the number of births as compared with the deaths increases every year, the movement of the population, if not quite stationary, at the present begins to show a downward tendency, as may be seen from the following table, which gives the number of births and deaths in France for the last ten years:—

Year.	Births.	Deaths.	Increase or Decrease.
1902	845,378	761,438	+73,940
1903	825,712	753,606	+72,106
1904	818,229	761,203	+57,026
1905	807,291	776,192	+31,099

OSTRICH-FARMING IN MADAGASCAR.—Ostriches were first imported into Madagascar in 1902, five pairs being offered to the Government and placed on a farm at Tulear. The beginning was hard, and a pair of birds died after a few months. The ostriches were then transferred to another farm, where their breeding became easier, owing to better climate and an abundant supply of grass. In 1904, the imported ostriches having reached their full growth, young ostriches were hatched, and in 1909 the farm had two hundred and twenty-eight birds. Trials with artificial incubation proved unsatisfactory, while natural incubation was successful. In the past few years, however, new incubators have been used, and the results have been promising. The acclimatising of the ostriches in the south-west of Madagascar has been entirely satisfactory, and the Government has just opened a new farm at Marovoay, near Majunga. The birds born in Madagascar are stronger than those which were imported. The race is improving, and it is expected that before long Madagascar ostriches will successfully compete with those of Cape Colony.

PRODUCTION OF PETROLEUM IN RUMANIA.—An Italian consular report from Bucharest states that the production of crude petroleum in Rumania during 1911 amounted to 1,544,072 tons, showing an increase of 191,665 tons, or 14·17 per cent. on the output of the previous year, which was 1,352,407 tons. The annual production of petroleum has increased steadily during the last five years, which was as follows:—

	Tons.
1911	1,544,072
1910	1,352,407
1909	1,297,200
1908	1,159,680
1907	1,129,080

MILKING MACHINES IN AUSTRALIA. — Milking machines, employed in New Zealand about four years ago, and since then much improved and developed in Australia, are coming into general use there, saving much time and labour for those engaged in dairying. The American Consul at Sydney says that demonstrations of these machines have been amongst the most interesting and popular features of agricultural shows in Australia, and he calls attention to several records of over one hundred cows being milked by these machines in less than two hours. The machines possessed the advantage not only of speed and economy, but also rendered the milking operation cleaner and more sanitary than when performed by hand. These machines are all made and worked on the natural principles of suction and compression, copying nature in the calf as closely as possible. One of these milkers is fitted with an automatic device called a "cut-out," which is only a float suspended on a valve spindle. Should the pail become full of milk this device comes into action, shutting off the power and ceasing to milk until the pail is emptied.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

THE LOOM AND SPINDLE: PAST, PRESENT AND FUTURE.*

By LUTHER HOOPER.

Lecture II.—Delivered March 4th, 1912.

SPINNING MECHANISM AND THE LOOM FOR AUTOMATIC WEAVING, PLAIN AND ORNAMENTAL.

In the present lecture I shall first deal briefly with the spindle in its later development from the domestic spinning-wheel of the sixteenth century to the machines of extraordinary capacity and exactness which supply the enormous quantity of yarn of all kinds required in the textile industries of to-day. This will clear the way for the further and more important study of the loom as used for automatic plain and ornamental weaving.

On the primitive spinning-wheel, you will remember, I pointed out that the spinning of the thread, and winding it on to the spindle, were separate alternate operations. On the more modern spinning-wheels the spinning and winding are made simultaneous by means of a little contrivance called a flier and bobbin attachment to the spindle.

The first historic hint we have of this invention is from a drawing in one of the sketch-books of the great artist-craftsman, Leonardo da Vinci. But it was not until nearly a century after his death, which took place in 1519, that the spinning-wheel with this clever attachment came into general use.

Fig. 22 shows Leonardo's drawing and the later spinning-machine attachments which have been derived from it.

In Leonardo's drawing No. 1 is called the *flier*. It is firmly fixed on the end of a shaft or spindle No. 2 A and 2 B. No. 3 is a small pulley also firmly fixed to the spindle between the bearings C and D. When this pulley is made to revolve very rapidly, by means of a cord or belt from a large wheel, the flier revolves

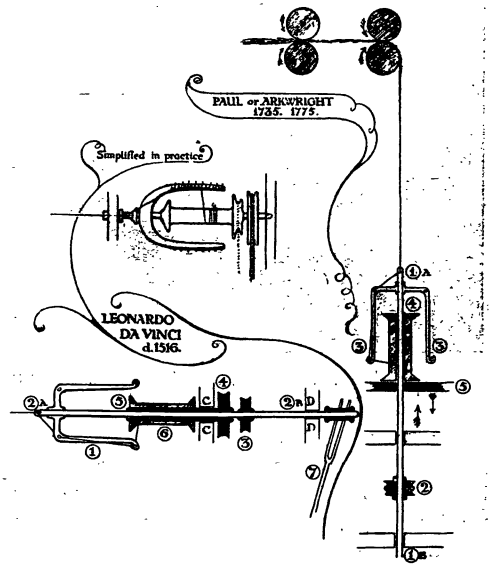

FIG. 22.—FIRST DRAWING OF BOBBIN AND THEIR ATTACHMENT FOR SPINNING-WHEELS.

with it and twists the thread which is passed through the hole in the spindle at No. 2 A.

No. 4 is another pulley, rather larger than No. 3. This pulley is fixed on a hollow shaft, which extends from the pulley to No. 5. In the hollow of this shaft the spindle can freely revolve, and on it the bobbin, No. 6, tightly fits.

Now, if the different-sized pulleys, Nos. 3 and 4, be actuated by cords from the same large wheel, the flier will revolve at a greater speed

* A large number of the illustrations are taken from Mr. Hooper's "Hand-Loom Weaving," and are reproduced by the courtesy of the publisher, Mr. John Hogg.

Hosted by Google

than the bobbin, the difference in speed being, of course, in proportion to the difference in size of the pulleys.

The result of this arrangement will be that, if the thread, twisted by the revolution of the spindle, be passed through the eyes in the flier, as in the drawing, and fastened to the bobbin, two operations will take place: (1) the thread will be twisted by the flier; (2) because the bobbin revolves at less speed than the flier the thread will be gradually wound upon the bobbin.

No. 7 appears to be a kind of fork fixed to the end of the spindle. If this fork were pushed to the right, the eye of the flier could be placed at any part of the bobbin, so as to spread the yarn evenly upon it.

Sooner or later this suggestion of Leonardo's was practically adopted, and the spinning-wheel, fitted with bobbin and flier, came into general use in Europe. The distaff and spindle, however, have not, even to this day, been altogether superseded.

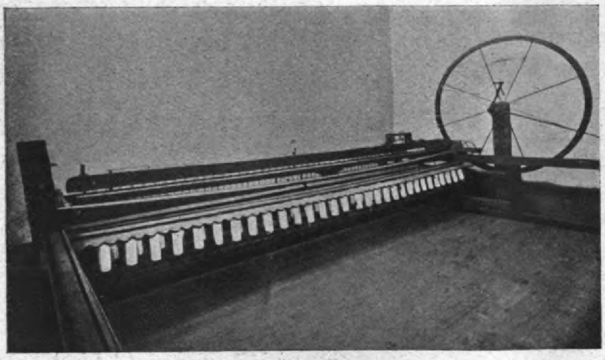

FIG. 23.—HARGREAVE'S SPINNING-JENNY.

A more compact and convenient contrivance for spreading the spun thread upon the bobbin is shown above Leonardo's sketch. In place of the fork for altering the relative position of the flier and bobbin, a row of small hooks is placed along the arm of the flier, by means of which the thread can be guided on to the bobbin at any part of its barrel. This is the twisting and winding arrangement with which the improved spinning-wheels of the seventeenth century in Europe were fitted up.

In order to compare it with Leonardo's sketch I have to the right of it (Fig. 22) made a diagram of the bobbin and flier of a machine spindle.

It is old-fashioned now, as a modification of it, called the ring spinner, has taken its place. The principle on which it works, however, is the same, so, as it is more convenient to compare with the original sketch, I prefer to use it.

Here Nos. 1 A and 1 B indicate the spindle which is caused to revolve by the pulley, No. 2.

The machine spindle is fixed vertically, a hundred or two being ranged on one machine.

The flier, No. 3, is fixed at the top of the spindle.

No. 4 is the bobbin standing on a shelf, No. 5. The shelf is made to rise and fall automatically as the thread is delivered to it from the flier. This is, therefore, a return to Leonardo's idea of the shifting spindle.

The spindle passes through the bobbin, but there is no hollow shaft for causing the bobbin to revolve. It simply stands loosely on the shelf, and when the thread from the flier is attached to it, the revolving flier drags the bobbin round at a less speed than its own, the weight of the bobbin acting as a brake. The thread is thus wound on more or less quickly, according to the weight of the bobbin.

In the ring spinner beforementioned the bobbin, or paper cop, is fixed firmly on the spindle and the flier is free. The flier runs on a ring which encircles the cop and drags upon it. This acts in the same way, as to winding, but makes it possible for the spindle to revolve at a much higher speed.

Although thus adopted for machine-spinning, the idea of a loose bobbin was not, I believe, a new one. Spinning-wheels had probably been previously fitted with loose bobbins, such as that shown in the diagram, above Leonardo's drawing. In this case the fixed flier is revolved by a pulley which is connected by a belt to a large wheel. The loose bobbin, if not heavy enough to act as its own brake, has a string which is lightly attached to some fixed part of the framework of the machine. This being passed over, the bobbin brake pulley can be easily made to regulate its drag to a nicety.

At the top of the diagram (Fig. 22) are shown two pairs of rollers, between which the fibres to be spun are being drawn out with such regularity as few spinners could boast of. In a machine such rollers are set in a series, at very accurate distances apart, and revolved in the direction indicated by the arrows. The front pair of rollers revolve more quickly than the second pair; the second pair than the third,

Hosted by Google

and so on. Consequently, as the fibres pass between the series, they are gradually drawn out into a fine fleecy rove which, between the front rollers and the spindle, becomes twisted into fine even thread.

This system of drawing out fibres by means of rollers was invented by Paul in 1735, and made practical by Arkwright in 1775, when he patented it. His right, however, was disputed, and on trial the patent was annulled, but his adaptation of the system was soon generally adopted.

When describing, in the last lecture, the primitive spinning-wheel and the distaff and spindle, where the spinning and winding-on were done alternately, I should, perhaps, have remarked that the finest threads were always produced in this manner. It is not surprising, therefore, that, very early in the history of machine spinning it was found that very fine, delicate threads could

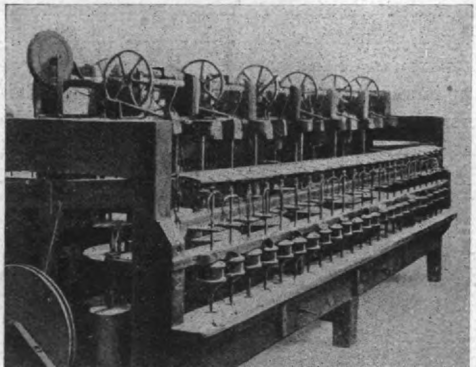

FIG. 24.—ARKWRIGHT'S WATER FRAME.

not be spun on the simultaneous principle. To overcome this difficulty, Crompton invented the mule machine, which imitates exactly the alternate twisting and winding of the primitive method of spinning. It was interesting to see, at the Anglo-Japanese Exhibition of 1909, the huge English machine of 250 spindles imitating with perfect precision the actions of a pretty girl, in the Japanese handicraft section, who was spinning gossamer thread on a primitive wheel, the same kind of wheel which had been in use in her country for a couple of thousand years or so, and which, we may hope, will be used for an indefinite number of thousands of years more by such charming little spinsters.

Messrs. Dobson & Barlow, Ltd., of Bolton, have courteously sent me five photographs of spinning machinery of great interest, which will require little explanation.

Fig. 23 is Hargreave's spinning-jenny.

Fig. 24 is Arkwright's water frame, so called because he used water as a motive power to drive it. It combines the *drawing rollers* with

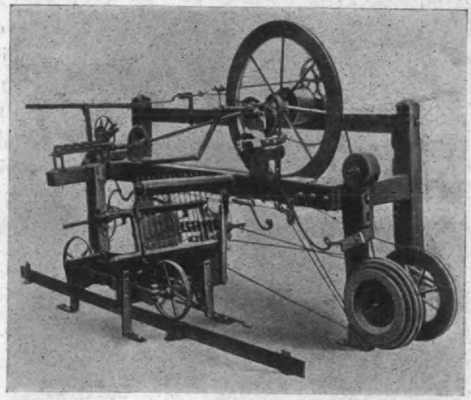

FIG. 25.—CROMPTON'S MULE. (Bolton Museum.)

the *flier and bobbin* attachment suggested by the spinning-wheel then in general use.

Fig. 25 is Crompton's mule, which he used in secret for some time, and mystified his neighbours by the quantity and quality of the yarn he produced.

Fig. 26 is a full-sized mule spinning-machine by Messrs. Dobson & Barlow, Ltd., of Bolton, which works on the same principle as Crompton's mule, and the Japanese girl I referred to just now.

Fig. 27 is a ring spinning-machine, working on the principle of this Italian peasant spinning-wheel. The driven bobbin and the loose flier.

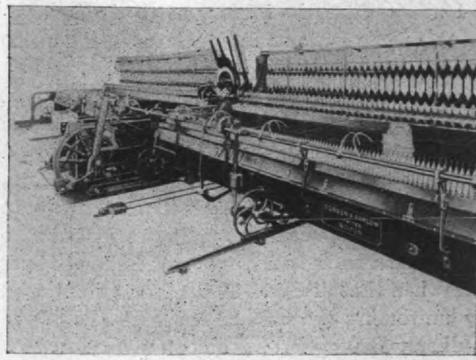

FIG. 26.—MODERN SPINNING MULE. (Dobson & Barlow, Ltd.)

[The lecturer here exhibited Italian and Belgian spinning-wheels, having a driven bobbin and a loose flier, and demonstrated how similar effects were obtained (1) by a separately driven bobbin

Hosted by Google

and flier, (2) a driven flier and loose bobbin, and (3) by means of a driven bobbin and a loose flier.]

In conclusion, as regards the spindle, although we may congratulate ourselves on the perform-

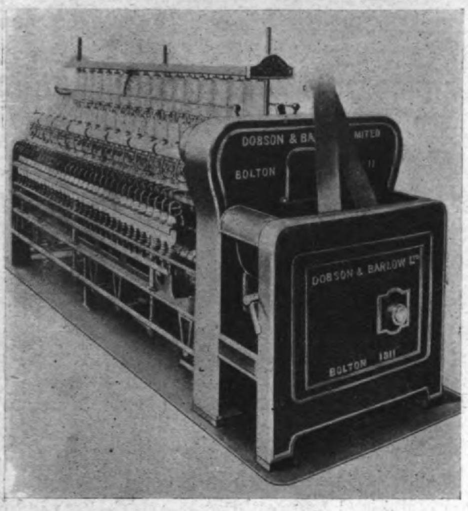

FIG. 27.—RING-SPINNING MACHINE.
(Dobson & Barlow, Ltd.)

ances of these wonderful thread-making machines and admire the inventive genius which has brought them to such perfection, it is interesting, though perhaps chastening and humiliating, to note that the untutored Hindoo spinner, squatting on the ground with a simple toylike spindle, can draw out and spin thread as fine, but infinitely stronger, than the most perfect machine of them all.

I now resume the inquiry as to the development of the automatic loom from the point arrived at at the end of my last lecture.

Four thousand years ago, more or less, probably at the time when the people of the Stone Age in Europe were cultivating flax and spinning and weaving its fibre into coarse cloth, the Chinese were inventing improvements in their primitive weaving appliances in order to adapt them to the weaving of an infinitely finer fibre than that of flax. This fibre was obtained by unwinding the case of the chrysalis of the mulberry-feeding moth, the caterpillar of which is familiarly known as the *silkworm.*

Chinese continuous written history goes back to that remote period, and tells that the annual festivals of agriculture and sericulture, which are still observed by the Chinese, were instituted by an Emperor and his wife, who themselves took leading parts in the festival, the Emperor ploughing a furrow and the Empress unwinding some silkworm cocoons. This practice their successors have continued to the present time.

This Empress is still highly honoured in China, and votive offerings are made to her at the festival. She is held in great regard as the benefactress who taught the Chinese how to prepare the silken thread for use and to weave it, thus enabling them to become the best and richest clothed people in the world. This pre-eminence they have maintained owing to their original monopoly, and expert knowledge of the cultivation and manipulation of the strongest, finest and most lustrous of all threads now called silk.

The silk fibre, on being unwound from the cocoon, is found to be a continuous, double thread of about the four-thousandth part of an inch in diameter. It takes from eighty to a hundred threads of natural silk to make up one thread of the size of the finest spun flax. It may be well understood, therefore, that special preparation of silk thread and specially delicate appliances are necessary for weaving it. This necessity proved to be, as is proverbially the case, the mother of many inventions, and there can be no doubt it is from the original

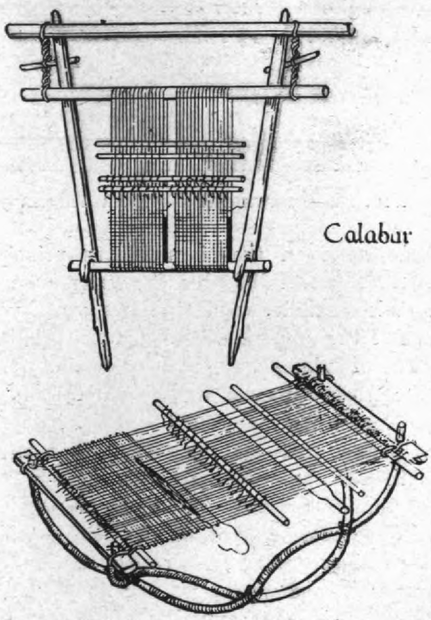

FIG. 28.—PRIMITIVE LOOMS.
(One fitted with two heddle rods.)

Chinese weaving appliances that almost all succeeding improvements in looms and loom fillings have been derived.

In order to describe the improvements in the loom required for weaving fine silk, reference must be made to Fig. 28, which shows a primitive loom fitted with a heddle rod for the purpose of raising the threads of the warp alternately with those raised by the shed stick.

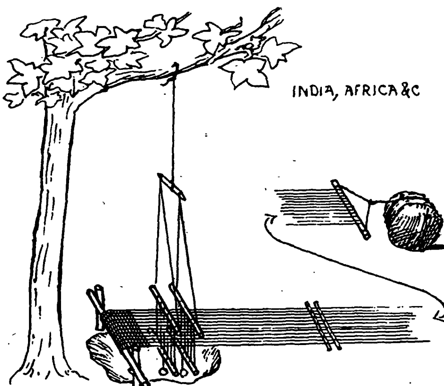

FIG. 29.—PRIMITIVE LOOM (India, etc.).

Two heddle rods in an upright loom would be no great, if any, advantage; but if the warp be placed horizontally the manipulation of the successive openings for the weft is much more convenient for the weaver, who sits at the end of the warp instead of in front of it.

Fig. 29 shows a very convenient form of Indian loom with the heddle rods suspended from the branch of a tree, and having the heddle loops connected with another pair of rods beneath the warp. The lower rods have strings hanging from them, each terminating in a ring. By placing one of his great toes in each ring, the weaver can pull down either set of loops at will, and make alternate openings for the shuttle carrying the weft. His hands are thus left free to manipulate the shuttle.

The addition of a long comb, equal in length to the width of the warp, was an immense improvement to the loom. The divisions in it were originally made of split reeds, hence it was called the reed, and is still so called, although the divisions are now always made of steel.

The effect of the long comb, with the warp threads entered in it, swinging in its heavy frame (see Fig. 30), was not only that the weft was beaten together more evenly and with less individual strain on the threads, but the width of the woven web was kept automatically the same.

Fig. 31 is a longitudinal section of the essential parts of a loom at the point of development now arrived at. It is lettered for reference. A is the roller on which the warp is wound in the first instance. B is the roller on to which the woven cloth passes. C C are the sticks preserving the cross which keeps the warp

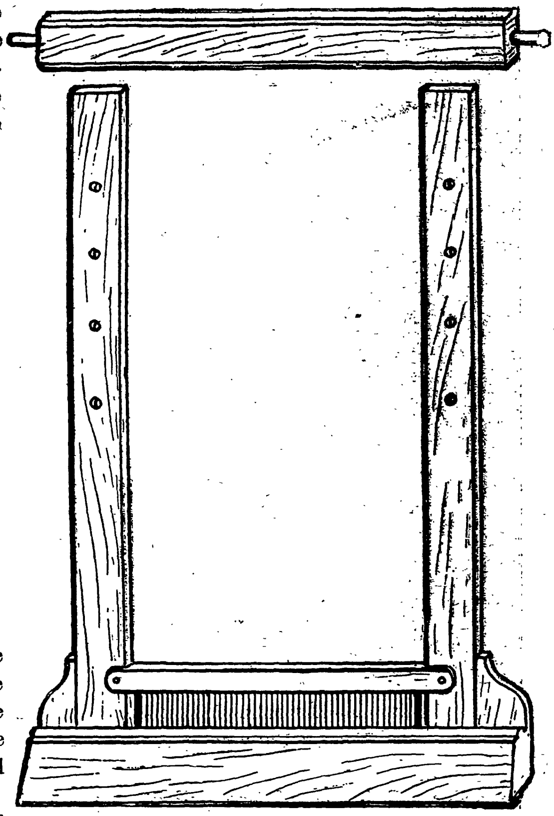

FIG. 30.—THE REED FITTED IN ITS FRAME.

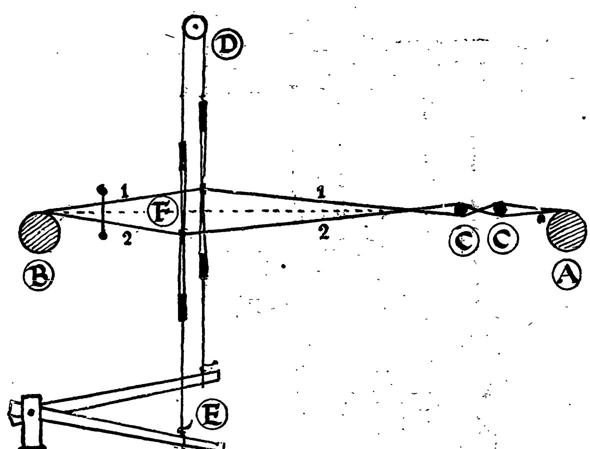

FIG. 31.—SECTION OF OPENED WARP.

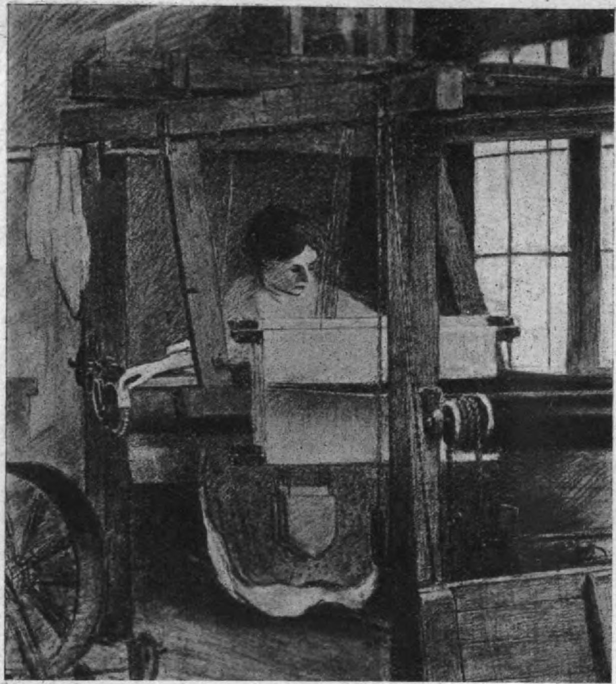

FIG. 32.—BETHNAL GREEN SILK WEAVER.
(From a Drawing by the Author.)

in order. D is one of two pulleys suspended from the top of the loom frame, over which cords pass after being attached to the ends of the top laths of the two heddles. At E are two treadles, which are tied to the lower laths of the heddles. Between the heddles and B the reed is shown suspended.

One treadle is represented depressed. This has pulled down one heddle and raised the other in consequence of the cord which passes over the pulley D. This movement has effected an opening in the warp at F, which, between the roller B and the reed, is wide enough for passing the weft through.

The successful weaving of plain silk necessitates a development of the loom to this point. It is, therefore, reasonable to credit the Chinese, who until the third century A.D. were the monopolists of silk and silk-weaving, with all these essential contrivances. Subsequently to the third century, these inventions spread through the East generally, and finally to Europe, first to Spain and Italy, then to France, Germany and England. It is remarkable that the loom of to-day, on which the very best silk fabrics are woven, should in all essential points be the same as the looms of ancient China.

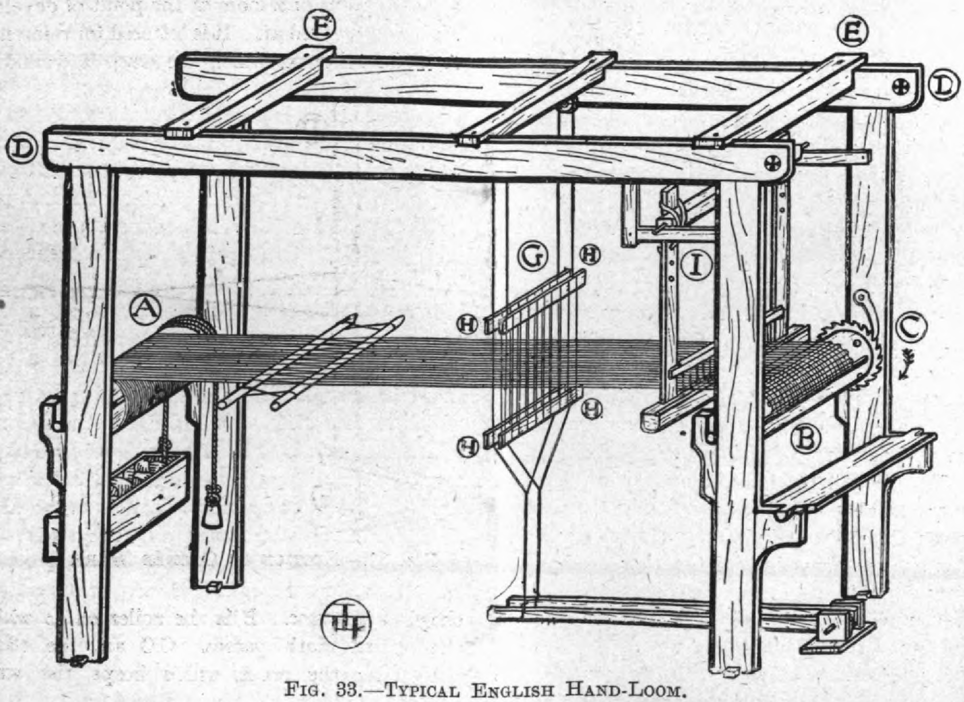

FIG. 33.—TYPICAL ENGLISH HAND-LOOM.

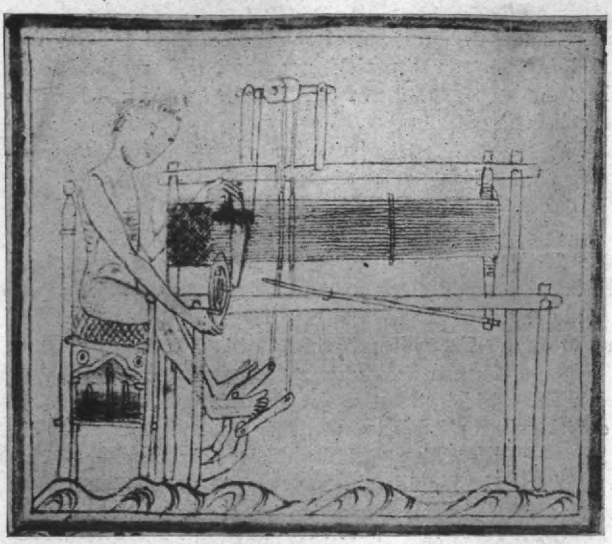

FIG. 34.—ENGLISH SILK WEAVER, FOURTEENTH CENTURY.
(From an old Manuscript.)

Fig. 32 is from a sketch I drew from life in a Bethnal Green silk weaver's workshop a few weeks ago. The weaveress is making a rich black satin, which will be all but perfect when it is cut out of the loom, and will require no after artificial finishing to make it ready for sale. The loom is arranged in the simple manner described, except that as the weaving of satin requires more heddles than plain silk, eight heddles instead of two only are shown.

The first impression given by Fig. 33, which is a diagram of an English loom, is one of sturdy strength. Strength and the perfect adjustment of the various parts of the loom are prime requisites where rapid and accurate weaving are desired.

Fig. 34 is from a manuscript of the fourteenth century, and represents an English silk weaver of the period at his loom. Whether the weaver is in correct costume I cannot say, but the loom and its fittings are quite recognisable, and like the loom of to-day, except for their slightness.

Fig. 35 is from a very old Chinese drawing. It is one cf a set of pictures representing the operations of sericulture. The first edition of the book from which it is taken is said to be of the twelfth century A.D.

It is the representation of a very perfect hand-loom for silk weaving. The weaver is shown sitting on the edge of a square hole in the ground, in which a set of treadles are seen. The framework of the loom is very carefully and solidly constructed. The front, or cloth beam, is shown with the reed hanging freely between it and the heddles. The back, or warp beam, is out of the picture, and the warp slants towards it after passing through the reed and heddles. The heddles themselves are very carefully fitted up, and are worked by means of the treadles in the pit, which are connected by cords to levers. These levers may be seen at the top of the picture.

The weaver, sitting in front of the loom, has just, by a blow of the reed, beaten up the weft, and is preparing to open the next shed and throw the shuttle which he holds ready in his right hand.

It will at once be noticed that the Chinese lcom (Fig. 35) has several heddles, instead of only two shown in the English loom (Fig. 33). In fact, there are two sets of heddles working together, one set having ten and the other five heddles.

The loom having two sets of heddles shows that some kind of pattern is being woven. As, however, at present I am speaking of the loom for plain or satin weaving, the second set of heddles need not concern us.

When the warp threads are very coarse and few in number, two heddles are sufficient for threading the warp, but when fine silk fabrics are to be woven, having three or four hundred threads to an inch, it is necessary to have several

FIG. 35.—CHINESE SILK-WEAVER'S LOOM.
(Ancient Chinese Drawing.)

Hosted by Google

pairs of heddles in order to prevent the leashes, through which the silk is threaded, from being too crowded. In this Chinese loom the front harness, as a collection of heddles is called, consists of ten separate heddles. In all looms the threads of the warp are passed through the eyes in the leashes of the heddles in regular order.

The first thread is passed through the first eash of the first heddle, the second thread through the first leash of the second heddle, then through the first of the third, and so on until all are filled.

[The lecturer here drew a diagram on the black-board illustrating the method of entering a warp in the harness.]

To manage this set of ten, or any even number of heddles, only two treadles are necessary for plain or tabby weaving. The heddles are first

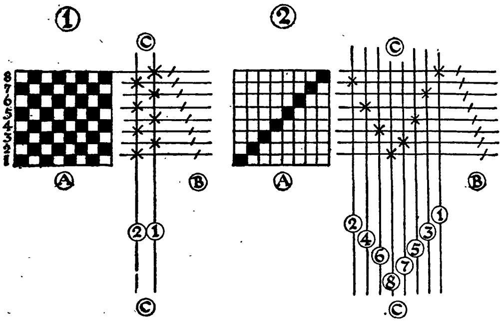

Fig. 36.—Plans of Tie-up.

joined together in pairs at the top, each pair having its two separate pulleys, as in the typical English loom (Fig. 33). The bottom laths of the first, third, fifth, seventh and ninth heddles are then all connected with one treadle, and those of the second, fourth, sixth, eighth, and tenth heddles are joined to the other treadle.

Now, it is manifest that if the first treadle be depressed half the warp, consisting of the first and all the odd-numbered threads, will be drawn down and the second and all the even-numbered threads will be drawn up. This will make the same opening for the weft as if there were only *two* instead of *ten* heddles.

In order to make this quite clear, the plan and tie-up of the pattern, as it is called, is given at Fig. 36.

This arrangement being at first made for plain tabby weaving of a close warp of fine threads, it would soon be discovered that by increasing the number of treadles and tying them to the heddles in different ways, the interlacements of warp and weft might be varied to an astonishing extent, and result in the production of an infinite variety of small patterns.

Fig. 37 gives, for example, four designs, which can be made on a loom fitted with four heddles and four treadles. If the threads of warp and weft are coarse enough, and the former white and the latter black, the designs would show as distinctly when woven as they do drawn out in the diagram.

There is not time, nor is it indeed necessary for our present purpose, to describe the way in which these designs are formed. All that is required is to note their possibility, and to show how this possibility affected the development of the loom itself.

A further examination of this ancient Chinese loom will show that, not only are there more

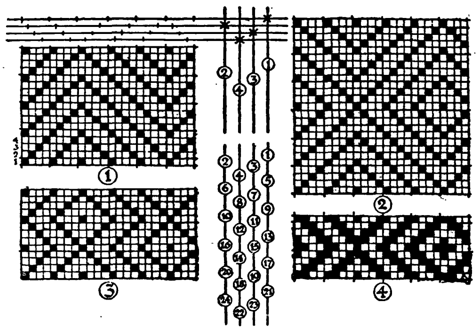

Fig. 37.—Simple Designs.

than two treadles in use, but instead of the heddles being tied together in pairs, as for plain weaving, each heddle is connected with one of a set of levers which in their turn are joined by a cord to the treadles.

Fig. 38 represents, without other details of the loom, two typical shedding motions, as any arrangement for opening the shed for the weft is called. In both these motions, as in the Chinese loom, the arrangement is one of heddles, levers and treadles connected together by cords. Below each diagram a longitudinal section of a loom at work is shown.

It is interesting to note that these ancient shedding motions are still in use. Silk fabrics made on hand-looms fitted with these motions cannot be equalled by webs woven on any machine-loom yet invented.

Fig. 39, which I drew from a Bethnal Green workshop, as it now is, shows a silk loom with precisely the same fitting up as the Chinese artist has drawn.

Hosted by Google

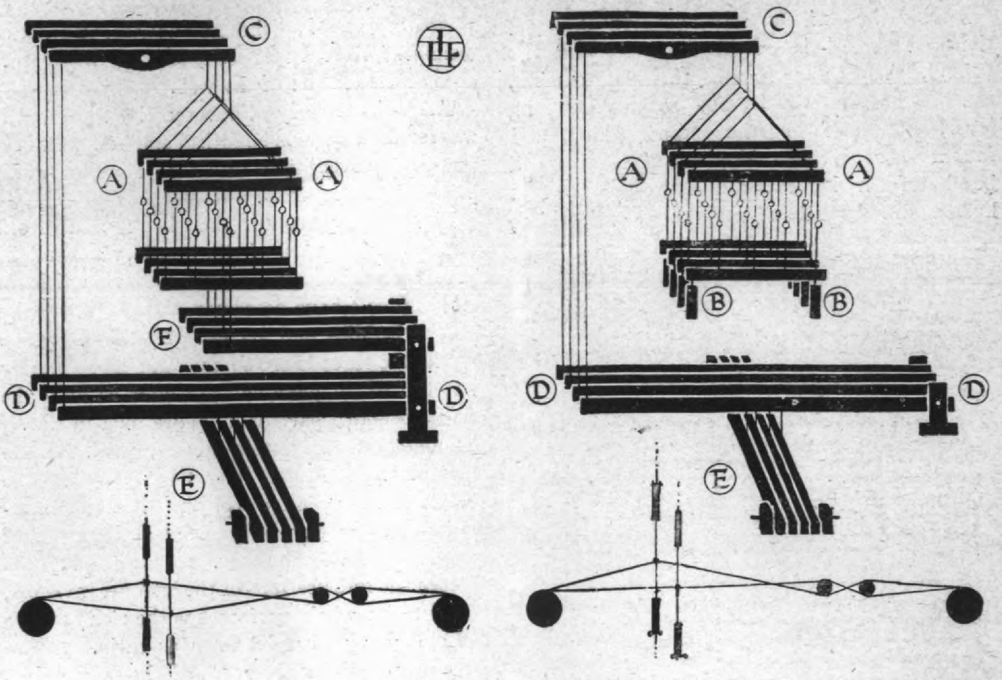

FIG. 38.—SHEDDING MOTIONS.

To return to the shedding motions (Fig. 38). In the right-hand figure the heddles A A have lead weights, B B, on their lower shafts. If, therefore, any of the four heddles be raised, as soon as they are released the weights will bring them down to their normal position. At the top of the loom, letter C, four short strong levers are fixed on an iron rod, which passes through a hole in their centres. From one end of each of these levers a heddle is suspended; and from the other end a cord hangs and connects each short lever with a long one, D D, which hangs across the loom below the heddles and above the treadles, which are lettered E.

It will now be seen that if any one or more of the long levers be tied to any one of the treadles, the weaver sitting in the loom has only to select and press a treadle in order to raise any arranged combination of warp threads for the weft to pass under, as it is carried by the shuttle through the opened shed.

The character of the shed made by this motion is shown below. The horizontal line is the normal position of the warp. The opening is made by raising certain selected threads.

An examination of the section below No. 2 will show that in it not only are certain threads of the warp raised, but all others are lowered, and the horizontal line of warp has disappeared. This is effected by adding to the motion another set of short levers, marked F, between the long ones and the heddles, and connecting the lower shafts of the heddles with them after

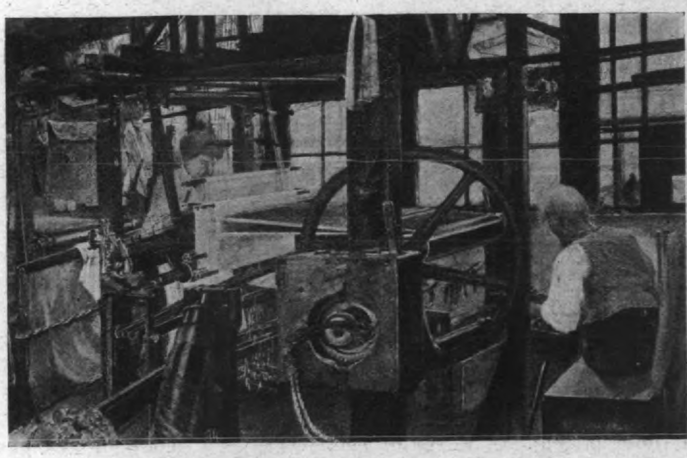

FIG. 39.—BETHNAL GREEN WEAVING SHOP, 1911.
(From a Drawing by the Author.)

Hosted by Google

removing the weights. If now, for example, the first thread be required to rise and the second, third, and fourth threads to sink, the first treadle will be tied to the first long lever, and also to the second, third, and fourth short levers. The result of this will be that when the treadle is depressed the first heddle will be raised and the second, third,

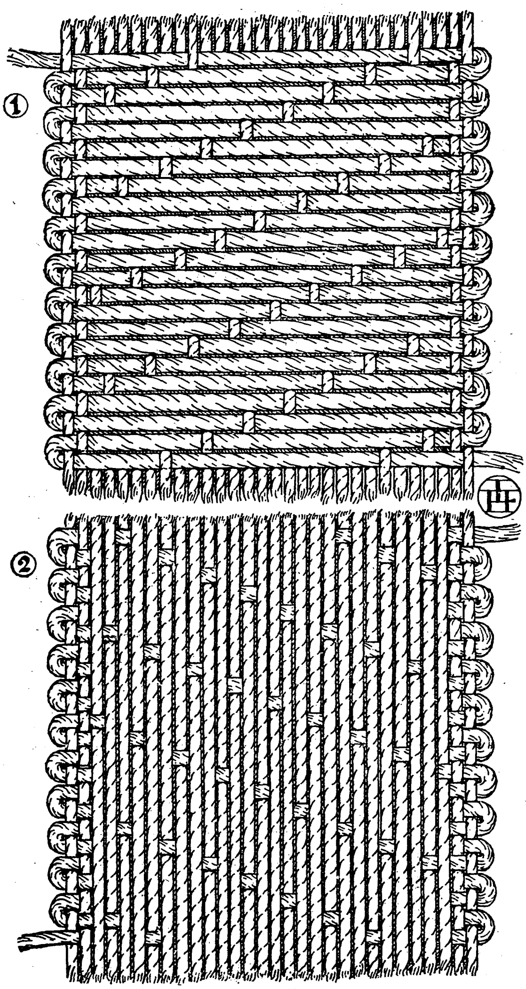

Fig. 40.—Satin Cloth (much enlarged).

and fourth heddles will sink, thus making the required shed.

These are typical shedding motions. All other motions are based on one kind or the other of these types, each kind having its advantages for certain classes of weaving.

I have already pointed out that such patterns as those of Fig. 37, woven of single threads, require the thread itself to be coarse in size in order to show as designs. But such designs, woven in fine silk, although indistinguishable as *ornament*, have a marked effect on the appearance of the texture of the web.

The Chinese early discovered this fact, and it was for their various beautiful and rich textures that the woven silks of China were so much prized in classic times.

Fig. 40 represents the back and front surfaces of a square of silk textile, which might have been woven in ancient China on a loom fitted up as I have described. It would require sixteen heddles and sixteen treadles to weave it, and the threads are so fine and lie so closely that the whole piece shown would be only the one-thousandth part of a square inch in size.

Looking at the lower square, which is the front of the material, it will be seen that the surface is nearly all warp, and that the intersections of the weft only occur at intervals of sixteen spaces each way. In cloth of this pattern the intersections of the weft are invisible, therefore its whole surface has the rich texture and glossy appearance known as satin. In the same proportion as the front of the satin web is nearly all warp, the back, of course, displays the weft. In pattern weaving these effects are called respectively warp satins and weft satins.

Satins may be made on different numbers of heddles, from five up to twenty-four. Fig. 41 shows several of them draughted on designers' ruled paper.

The next step in the evolution of the loom was to adapt it for distinct pattern weaving. This was effected by adding a second set of heddles to the harness, making it what is called a *compound* harness.

This compound mounting is shown in the Chinese drawing. The front set of ten heddles is for making the groundwork of the fabric, and the back set of five is for raising the *figure*, as the design is usually called in weaving.

Here is a very simple figure (Fig. 42), which will well illustrate the method of double harness pattern weaving. It is of a kind, too, of which the Chinese are very fond, having spots of ornamental shape powdered over a plain ground. Moreover, it could be woven on a loom fitted up exactly as in the Chinese picture.

The ground of this design is a plain tabby silk. I have already shown how this can be woven in a harness of ten heddles by means of two treadles. Five other treadles would, however, have to be added in order to work the figure harness, one for each heddle.

For double harness weaving, too, the leashes of the heddles of the front harness have an

important peculiarity which must be described; for, though simple, it plays a most essential part in all pattern weaving with compound harness.

In this class of weaving each warp thread passes first through the eyes of the figure harness and then through those of the front harness, which makes the ground. Now, if both harnesses are alike fitted with leashes having the ordinary short eyes, only the front one can affect the shed. This is because any threads raised by the back harness are prevented from effectually rising in the reed by the leashes of the front harness.

If, however, the front harness eyes are made long enough to allow the warp threads to be lifted, the back harness will be free to affect the shed at the same time as the front harness, or to affect it alternately, as may be required. The diagram, Fig. 43, will make this clear.

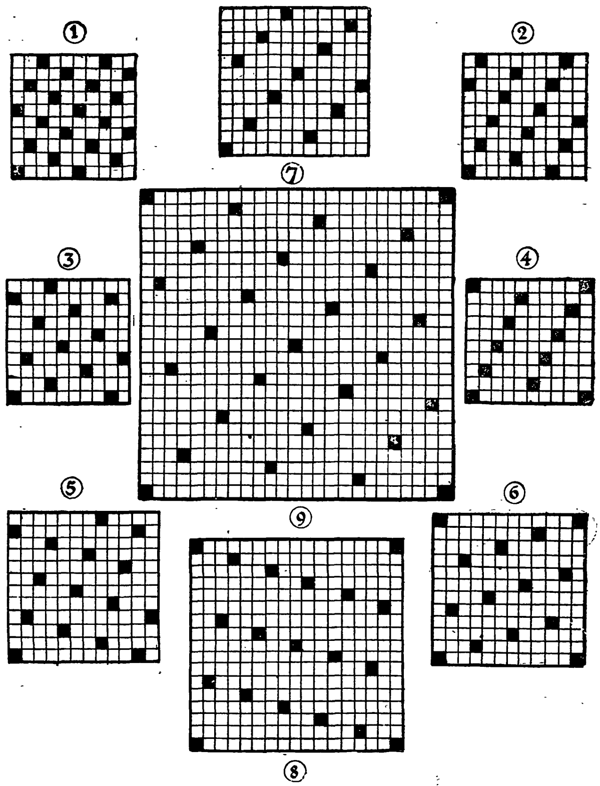

FIG. 41.—SATIN TIES.

If, now, we turn again to Fig. 42, the part played by the figure harness can readily be explained.

The points to notice are: (1) Two extra wefts are required for weaving in the design which has two separate colours of its own; (2) the figure is formed by allowing the coloured weft, in certain places, to pass over two threads of the warp instead of one; (3) the necessity for five heddles in the figure harness is to be gathered from the fact that five different combinations of pairs of rising threads are required to complete the design; (4) as the figure throughout is made by two threads rising together, two threads together may be entered in each eye of the figure harness.

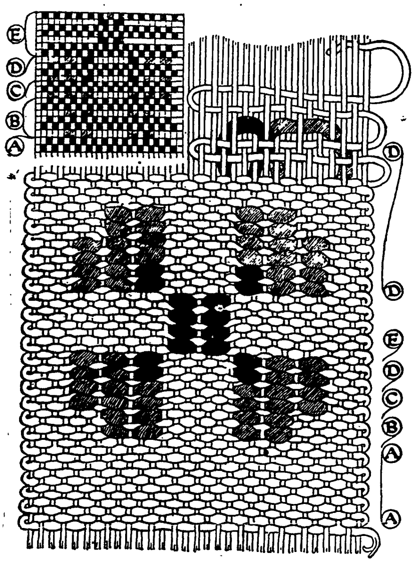

FIG. 42.—DOUBLE HARNESS WEAVING.

If this explanation is clear, it is only necessary to add that in silk weaving, not only *two*, but sometimes as many as *twenty* warp threads are entered in each leash eye of the figure harness. Therefore it is evident that the possible scale of ornamentation and scope for the designer are immensely increased. For instance, this figure woven on two threads, as explained, on a fine silk warp of 400 threads to an inch would only occupy the sixteenth of an inch in width and height, but if twenty threads were entered together in each leash eye of the figure harness the size of the ornament would be increased ten diameters, and would occupy nearly a square inch of surface.

There is, therefore, represented in this old Chinese drawing (Fig. 35) a very perfect loom for weaving small designs of simple

Hosted by Google

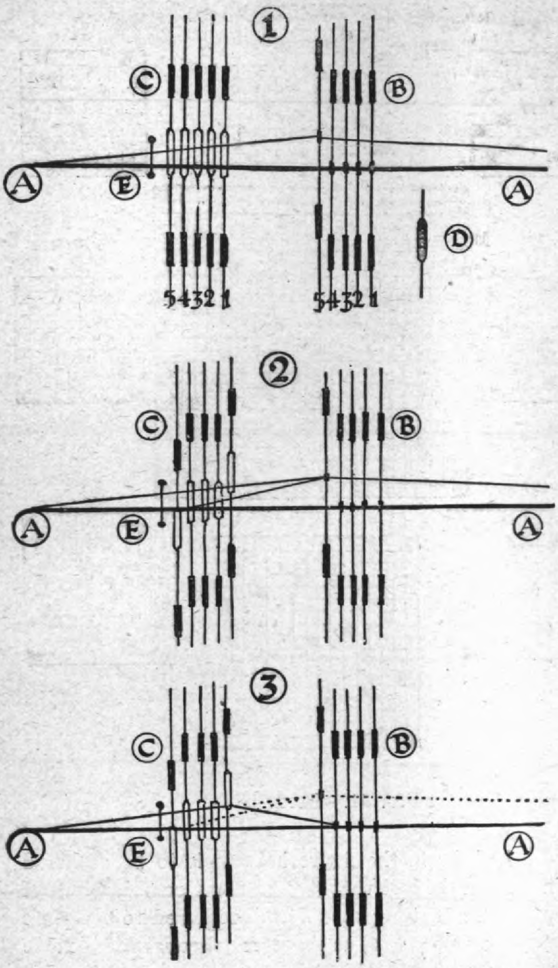

FIG. 43.—DOUBLE HARNESS SHED SECTIONS.

construction. The limit of size and elaboration of the pattern in this kind of loom is, however, reached when the number of figure treadles and heddles becomes too great for practical use. There is no evidence of the Chinese having endeavoured to weave with an elaborate system of heddles and treadles such as were ingeniously devised in England in the eighteenth century, but which, being very difficult to fit up and manage, were soon superseded.

Fig. 44, taken from the same Chinese book as the foregoing Chinese drawing, shows, in a compound loom, a figure harness of entirely different construction, which is evidently made on the same principles as the perfected European draw-loom of the eighteenth century, on which were woven the most sumptuous and intricate webs which the weaver's art has ever produced.

In this representation of a pattern weaving loom, instead of the small figure harness of five heddles, a large one of quite different build is shown. Over this harness an assistant weaver, perched aloft at the back of the loom, is presiding. He is, in fact, drawing up, according to an arranged plan, certain groups of threads required for the formation of a pattern. The all-important part of this picture is the portion of the loom over which the assistant weaver is presiding.

Taken by itself, it is a complete loom harness of remarkable capacity. In fact, for automatic pattern weaving, a loom fitted with this contrivance for raising the warp threads only is as complete in its way as the perfected primitive loom is for tapestry weaving, as I pointed out in the last lecture.

Although the Chinese picture represents what is unmistakably a draw-loom apparatus, it is not clear enough in detail to describe the machine from. I must, therefore, have recourse to a diagram (Fig. 45).

Here, at No. 1, I have represented in diagrammatic form the simple draw-loom, and at No. 2 a design on ruled paper suited to its capacity, which is purposely kept very limited for the sake of clearness.

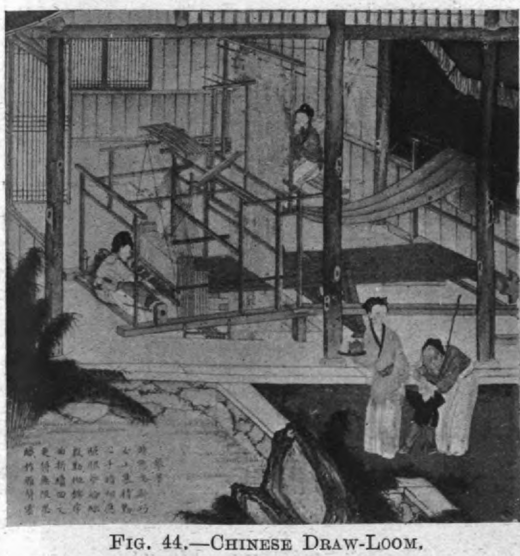

FIG. 44.—CHINESE DRAW-LOOM. (From an ancient Drawing.)

Hosted by Google

The whole mechanism of the draw-loom centres in the comber board and leashes which hang in the loom in place of the ordinary harness of few or many heddles. The advantage of the comber board monture over the ordinary heddle harness is that whatever width a design may be, even to the whole extent of the warp, the monture takes up no more longitudinal space in the loom than a harness of a few heddles.

The comber board, No. 3, is simply a board pierced with a number of holes equal to the number of threads of the warp which it is to govern.

In each of these holes a separate leash is hung. Each leash has a long, thin lead weight at its bottom end; and in its centre, instead of a string loop, a glass eye called a mail, through which a warp thread is entered.

The comber board in the diagram is only pierced with seventy-two holes, consequently it is only for a warp of seventy-two threads. If it were for seventy-two thousand threads of fine silk it would not take appreciably more space in the loom.

The draughted design at No. 2 is made on eighteen lateral squares, so that it would repeat four times in the width of the web to be woven.

The word "comber" board is derived from an older word, "camber," which used to signify the repeats of a design as regards width. The board was called a camber board because the holes pierced in it were accurately apportioned to the number of threads in each pattern repeat, and the width of the total number of holes was the same as the width of the warp.

In this comber board (Fig. 45) there are holes for four repeats, of eighteen leashes, but only six leashes of each repeat are shown in position, as more would confuse the drawing.

The bottom board of the triangular box, C, is pierced with eighteen holes, the same number as that of the threads in each repeat of the design.

Let us suppose the comber board to be filled with leashes, one suspended in each hole; also that eighteen cords are hanging through the holes in the triangular box at D.

The monture builder now connects, with fine cord, the *first*, *nineteenth*, *thirty-seventh*, and *fifty-fifth* leashes, which are the *first* in every repeat, with the *first* hanging cord at D.

He next takes the *second* leash in each repeat, and connects it in like manner with the *second* cord at D.

He proceeds thus in regular order to connect *leashes* and *top cords* until he reaches the last of the repeats, leashes *eighteen*, *thirty-six*, *fifty-four* and *seventy-two*.

When this work is done it is apparent that if any *one cord*, at D, is drawn up into the triangular box the corresponding leashes in *every repeat* will be drawn up through the comber board to a corresponding height.

Moreover, if seventy-two threads of warp are entered in the leash eyes, the selected leashes

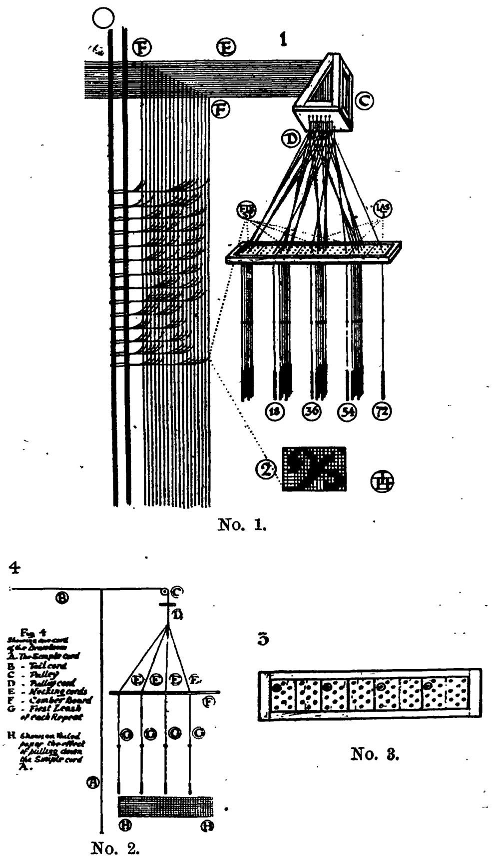

Fig. 45.—Draw-Loom Diagrams.

as they rise will raise the threads necessary for the formation of the pattern shed.

This is the essential portion of the draw-loom, and so far is it from being obsolete that all the pattern-weaving looms of to-day, whether worked by hand or power, are identical with it. Thus the immense textile industry of modern times is indebted to, and linked with, the invention and industry of ancient China.

Vast numbers of different methods of drawing up the cords of the loom were no doubt practised

Hosted by Google

in the East. Most frequently, as in the Chinese picture (Fig. 44), the weaver's assistant who did this work sat above the loom drawing the cords line by line according to a written or painted draught.

There is no evidence to show what form this part of the loom had assumed when the art of silk pattern weaving was introduced into Sicily in the twelfth century. The rapid development of silk weaving in Sicily and Italy, which we know took place, makes it more than probable that the convenient method of drawing the cords from the side of the loom, as shown in this diagram (Fig. 45), was invented soon after the art was introduced. However, *when* introduced or *by whom* invented, it is certain that it was on looms mounted and fitted up in this manner that the masterpieces of the weaver's art, made in Europe from the thirteenth to the eighteenth centuries, were produced.

I resume the explanation of the diagram of the draw-loom (Fig. 45) at the point D, where the eighteen cords are seen to enter the triangular box, C. This box is fitted up with pulleys, eighteen in number. Each cord passes over a pulley and is seen again at E. The collection of eighteen cords, called the tail of the monture, is then securely fastened to the wall of the workshop, or some convenient strong post.

Between F and F another series of eighteen cords, called the simple, is tied to the tail series and fastened to the ground.

A simplified diagram, showing one cord in all its parts, is given in No. 4.

Now it will at once be seen that if the cord, A, be pulled down by an assistant standing at the side of the loom, the eyes of the leashes, G, through which the warp threads pass, will be pulled up.

It is necessary, then, in the *simple*, to have as many cords as there are threads, or groups of threads, in each repeat of the comber board. And it is possible to weave on the loom any design, of whatever length, that can be drawn on the number of threads arranged for in each repeat.

If we turn to the design No. 2 we shall see that it is drawn on eighteen squares, and if we compare the design with the loops tied from the large guiding cords to the separate cords of the simple, we shall see that they agree. The black squares in the design represent a tie. Take the first line, beginning at the left-hand side. Here are six black squares. If we follow the dotted line to the first cord of the simple, a group of six ties will be found. Then, passing over six cords, a group of four ties are found which correspond with the four black squares in the third division of the sketch.

By means of these loops the draw-boy, as he was called, selected the cords for pulling down, and, having gathered them together on the prong of a large fork, to which a lever was attached, he pulled the lever and drew the leashes up, thus opening the shed for the weaver's shuttle.

The design had to be tied up on the simple cords line by line before weaving could commence; but when this was once done the draw-boy had only to pull the cords, in regular sequence, in order to repeat the design continuously in the length of the web.

On this mounting of the loom entered with single threads of warp any possible interlacements of warp and weft can be worked out. It may well be called, therefore, the most perfect loom. Its only limitation is in the size of the design. It would require a simple of 400 cords to tie up a design one inch wide for a silk web 400 threads to an inch.

This difficulty was surmounted by adopting the compound harness arrangement I have already described. It is shown in the Chinese drawing of the pattern-weaving loom (Fig. 44).

If threads, entered singly in the front harness, are lifted in tens by each leash of the figure harness, the design will be woven ten inches wide instead of one inch. The simple and tie-up being no more extensive or complicated.

More elaborate interlacements of warp and weft were arranged for by dividing the comber board into two or even three parts, each governed by a separate set of simple cords, as well as by adding more warps and rollers to the loom, and additional harnesses of heddles for binders and stripes of satin, tabby or tobine effects. In fact, there seems to be no limit to the different combinations the skilful designer may invent and provide for in this most perfect and adaptable of all craftsman's tools, the compound draw-loom.

In my third lecture I shall describe the *Jacquard* machine, and some other important weaving inventions of the eighteenth century, the evolution of the *power-driven* loom, describe a new *circular* loom, and indicate some possible developments of the weaving-machines of the future.

ZOOLOGICAL GARDENS.*

There are now more than a hundred public zoological gardens in existence, of which twenty-eight are in the United States, twenty in the German Empire, five in England, one in Ireland, and none in Scotland. I hope that the efforts of the Zoological Society of Scotland will be successful, and that before many months are over there will be a zoological park in the capital of Scotland. There is no reason of situation or of climate which can be urged against it. The Zoological Society of Scotland would have the great advantage of beginning where other institutions have left off; it would be able to profit by the experience and avoid the mistakes of others.

The Zoological Society of London would welcome the establishment of a menagerie in Scotland, for scientific and practical reasons. I may mention two of the practical reasons. The first is that Great Britain labours under a serious disadvantage as compared with Germany with regard to the importation of rare animals. When a dealer in the tropics has rare animals to dispose of he must send them to the best market, for dealing in wild animals is a risky branch of commerce. If he sends them to this country there are very few possible buyers, and it often happens that he is unable to find a purchaser. If he sends them to Germany, one or other of the twenty gardens is almost certain to absorb them, and failing Germany, Belgium and Holland are near at hand.

Were there twenty prosperous zoological gardens in Great Britain they could be better stocked, at cheaper rates, than those we have now. The second practical reason is that it is a great advantage to menageries to have easy opportunities of lending and exchanging animals; for it often happens that as a result of successful breeding or of gifts, on the one hand, or of deaths, on the other, a particular institution is overstocked with one species or deficient in another.

Menageries are useful in the first place as educational institutions, in the widest sense of the word. For that reason zoological gardens should be associated in some form with elementary and secondary education. Menageries provide one of the best schools for students of art, for nowhere else than amongst living animals are to be found such strange fantasies of colour, such play of light on contour and surface, such intricate and beautiful harmonies of function and structure. They also provide a rich material for the anatomist, histologist, physiologist, parasitologist, and pathologist; but there remains the fundamental reason for their existence, that they are collections of living animals, and therefore an essential material for the study of zoology.

Systematic zoology, comparative anatomy, and even morphology, the latter the most fascinating of all the attempts of the human intellect to recreate Nature within the categories of the human mind, have their reason and their justification in the existence of living animals under conditions in which we can observe them. Certainly we like to have many species, to have rare species, and even to have new species represented in our menageries. But what we are learning to like most of all is to have the examples of the species we possess, whether new or old, housed in such a way that they can live long, and live happily, and live under conditions in which their natural habits, instincts, movements, and routine of life can be studied by the naturalist and enjoyed by the lover of animals. Space, open air, scrupulous attention to hygiene and diet, the provision of some attempt at natural environment are receiving attention that they have never received before.

However we improve the older menageries, and however numerous and well-arranged the new menageries may be, they must always fall short of the conditions of Nature—another reason for the making of zoological sanctuaries throughout the world. If these are devised for the preservation of animals, not merely for the recuperation of game, if they are kept sacred from gun or rifle, they will become the real zoological gardens of the future, in which our children and children's children will have the opportunity of studying wild animals under natural conditions. We must use all avenues to knowledge of life, studying the range of form in systematic museums, form itself in laboratories, and the living animal in sanctuaries and menageries. And we must keep all avenues to knowledge open for our successors, as we cannot guess what questions they may have to put to Nature.

* Extracted from the Presidential Address of Dr. Chalmers Mitchell to the Zoological Section of the British Association.

OLD DUELLING DAYS IN CALCUTTA.

Some recent reflections in an Indian periodical on the practice of duelling as carried out in the early days of John Company prove, from the numerous rencontres that took place in the eighteenth century, that the custom obtained as firm a footing in India as it had in Europe, whence, of course, it was imported. In those days the healthy occupations and outdoor exercises which now serve to distract and fill up leisure time were often wanting; gambling and drinking were far too prevalent, and there was a lack of the social and humanising influence of cultured ladies which is found nowadays in nearly all up-country stations and, of course, to a much greater extent in the towns. It is said that formerly a young officer could not go through his period of service without being subjected to one or more challenges, and even the mildest-mannered seniors were occasionally the worst offenders.

There were two "trees of destruction" at Kidderpore, where, in the early hours of the morning, "affairs of honour" were customarily settled. Sometimes, in case of a fatal result, cholera was given out to be the cause of death,

Hosted by Google

and the funeral was carried out with military honours.

The great majority of duels were fought with pistols, but the *Calcutta Chronicle* of May 21st, 1793, notices an affair which came off with small swords within an apartment. This, however, was altogether exceptional. Military men were, as might be supposed, the most inveterate supporters of the practice, but civilians were almost as frequently involved. J. H. Stocqueler, editor of the *Englishman*, and J. Silk Buckingham, of the *Calcutta Journal*, were in their days concerned in several duels. In 1837 a dispute arose between Stocqueler and Captain Sewell as to some criticism in the former's journal regarding the quality of the food supplied to the inmates of Kidderpore House, which was a Government institution. The editor, refusing to withdraw his animadversions, was challenged by the captain, who secured the services of a brother officer as second, Mr. Stocqueler being attended by Mr. Buckingham. The meeting took place at Howrah. The soldier fired first and missed, whereupon the civilian fired his pistol in the air, and the affair was settled by the seconds declaring that "honour was satisfied."

Mr. Stocqueler was a clever and indefatigable *littérateur*. One of his last experiences, towards the close of a long and busy life, was to enter the India Office in the early seventies as a temporary clerk, on the nomination of the late Duke of Argyll. He did not, however, remain there long, and died shortly after.

One of the most famous and historic encounters of early days was that between General Clavering and Mr. Richard Barwell in 1775. From the account given by Mr. Beveridge in his volume on Backergunge, it appears that Barwell held the lease of a couple of Government salt farms which he sub-let to two Armenians, on condition that his personal consideration in the transaction was to be a bonus of a lakh and 25,000 rupees (£7,812). Unfortunately, even this handsome profit did not appear to satisfy him, for one of the Armenians subsequently complained that Barwell had turned him out and re-let the farm to someone else for an additional lakh of rupees (£6,250). When taxed with being guilty of this discreditable transaction, Barwell boldly contended that he was within his rights. Accordingly, at a meeting of Council, General Clavering rose and called on Mr. Barwell to say how he held such a proceeding to be consistent with his oath to the Company. Barwell, probably conscious that he had no case, tried to ride off by grossly insulting his accuser. He replied with heat, "Whoever says I have done anything inconsistent with my oath to the Company is a rascal and a scoundrel."

Clavering, incensed at the insult, clapped his hand to his sword, whereupon Barwell bowed and retired. At the ensuing duel the General fired and missed; but Barwell declined to fire at all, a proceeding which in those days seems to have had a particularly irritating effect on any antagonist. In fact General Clavering threatened, if Barwell continued in his refusal, to fire a second pistol; but in the end, owing, it is said, to the intervention of the seconds, matters were peaceably arranged by Barwell's promise to apologise. A romantic element to the story is supplied by the fact that Barwell was much attached to the General's daughter.

The encounter between Hastings and Philip Francis was still more famous. The conduct of the latter had for some time occasioned the Governor-General the gravest displeasure, and in consequence the latter wrote in one of the minutes of Council a severe denunciation of Francis and his reprehensible ministerial misdeeds. Out of this a challenge would be the inevitable result, and, apprehending this, Hastings sent Mrs. Hastings out of town and waited till Francis, who was suffering at the time from a slight attack of fever, was sufficiently recovered to attend Council. Then Hastings read out the accusatory document in all its severity, and the same evening received a challenge from Francis. The parties met the next morning in the vicinity of Belvedere, the seconds being Colonel Watson and Colonel Hugh Pearse, and the distance measured out was fourteen paces. On the word being given both men fired, and Francis fell. Hastings immediately ran to the side of Francis, saying that, if anything serious happened to his opponent, he would surrender himself to the Sheriff. Pearse ran to summon assistance, and returned with a sheet which was wrapped round the wounded man in order to stop the bleeding. He was taken in Pearse's carriage to Belvedere, where he was attended by two doctors, one being Hastings' own medical attendant.

Most of the above facts are corroborated by Warren Hastings' own hand in a very interesting letter addressed by him to his wife, beginning "My dear Marian," and exhibited in Case IV. in the British Museum, in the Manuscript Saloon adjoining the Grenville Library.

In those days there stood, not far from Calcutta, an institution known as the Baraset Military College, where young men from English public schools were prepared for cornetships in the Company's army. What would be now termed "ragging" was then rife, and General Sir J. B. Hearsey, writing of his college days, says:—

"I usually studied Urdu by candle-light as my days were spent in sport, and I was often disturbed by the young men who saw me thus employed. They threw clods into my room, which frequently hit me or my *munshi*, or broke and extinguished my light. One close night, being disturbed in this manner, I ran hastily to the open window and caught a glimpse of one of the cadets endeavouring to hide. I shouted out, 'I know who you are, and you shall hear from me to-morrow morning.' About two minutes afterwards the door opened, and a young man came in smiling and innocently remarking, 'So, as usual, you are studying at night.' In him I instantly recognised the offender, and, seizing the thick quarto volume of Gilchrist's Dictionary, I struck

him down with it, telling him to quit the room, and I should be ready to give him the satisfaction due from one gentleman to another on the morrow. However, he never called again."

Mr. Keene tells of two jovial brothers, one an officer of the Bengal Cavalry and the other a kindred spirit in the line, who happened to meet at the mess-table of a native regiment a pair of cadets who were on the way up country to join for the first time. The apparent simplicity of these youths tickled the frolicsome brothers, who were warm supporters of the institution of duelling, and when the two cadets got into a dispute over a game at cards, the wicked seniors declared that single combat could only satisfy honour. It was faintly objected that the night was too dark, but this was overruled by the senior brethren declaring that each of them would hold up a wall lamp. Accordingly the party proceeded to the mess compound, but on the way the two cadets contrived to nudge each other, and, without being observed, to decide upon a small conspiracy. The combatants were placed opposite each other with loaded pistols in their hands at twelve paces, while their friendly mentors took up the other corners, each holding a light. The word was given, the youngsters fired, and with a crash of glass each lamp fell shattered and extinguished to the ground from the well-aimed discharge. It is not recorded what the two senior officers said or thought of the affair.

Many other noteworthy encounters are on record, but the decay of duelling in England was inevitably followed by its discontinuance in India, though the latter was very gradual. It was not till 1843, when an association of officers, civilians, noblemen and others was formed to discourage duelling, that the rise of a new public opinion succeeded in overcoming the bad but time-honoured custom.

TRADE OF THE PORT OF LE HAVRE.

As a commercial port, Le Havre is the second in importance in France. Next to Marseilles, where the total movement of shipping amounted to 15,751,797 registered tons in 1909, that of Le Havre shows a total of 12,251 ships and 9,265,897 tons during the same period.

Next in importance to Le Havre follows Dunkerque, with a movement of upwards of four million tons annually, Bordeaux slightly less, and Rouen with 3,800,000 tons per annum.

During 1910, 12,343 ships, with an aggregate of 9,571,904 tons burden, entered and left Le Havre. Last year the total tonnage was 10,038,650, which, compared with that of the previous year, shows an increase of 466,746 tons in favour of 1911. This increase, in a great measure, may be attributed to the deficiency of the grain crops in France, which necessitated the importation of foreign corn.

The trade at this port has made remarkable progress during the last ten years, when it was 5,747,000 tons as compared in round numbers to 9,572,000 tons in 1910, and upwards of ten million tons in 1911, showing an increase of 66·55 per cent. and 74·0 per cent. respectively.

The large number of manufactories of various kinds at Le Havre contributes greatly to its prosperity. The total quantity of coal imported here is estimated at between eight and nine hundred thousand tons annually.

In 1909 the total quantity of merchandise imported and exported and the value of the trade at this port were :—

	Tons.	Francs.	
Imports .	2,221,962	1,502,100,000 =	£60,084,000
Exports .	876,606	1,287,000,000 =	£51,480,000
Totals .	3,098,568	2,789,100,000 =	£111,564,000

The value of the imports to Le Havre by sea constitute about 29 per cent. of that for the whole of France.

The revenue of the Custom House at this port in 1909 amounted to 80 million francs (£320,000), or 38 per cent. of the total from that source in France.

Le Havre may be termed the Liverpool of France. Only 141 miles from Paris, it is a convenient port for the great French steamship companies, such as the Compagnie Générale Transatlantique, who make it the starting-place for New York, etc. It is also the great market for cotton in France, 182,975 tons of which were imported from America in 1910, as compared with 276,759 tons for the whole of France. This port is also the principal market for coffee, importing 127,659 tons, out of a total of 165,055 tons for the whole of France.

Amongst some of the articles imported may be mentioned cacao, 51,216 tons, as compared with 61,015 tons (total imports to France); india-rubber, 11,109 tons, out of 19,977 tons; and copper, 65,295 tons, out of 98,469 tons.

The average value of a ton of merchandise at the five principal ports in 1909 was as follows :—

Le Havre . . .	676 francs	= £27 0 10	per ton.
Marseilles . .	391 ,,	= £15 12 10	,,
Dunkerque . .	413 ,,	= £16 10 5	,,
Bordeaux . . .	171 ,,	= £6 16 10	,,
Rouen . . .	77 ,,	= £3 1 8	,,

The French flag figures for about 33 per cent., as regards tonnage (registered) in the movement of shipping at this port.

The total number of the passengers carried in 1911 by the cross-Channel steamers of the London and South-Western Railway Company was 50,544, of whom 24,482 were landed at Havre, and 20,062 at Southampton.

The passenger traffic between Havre and New York last year shows a decrease of 12,610, as compared with the number carried in 1910. The number carried in 1911 was 60,530, being 21,662 cabin passengers and 38,868 emigrants.

The number of passengers from New York landed at Le Havre during the same period was 42,606, of whom 30,513 were third-class.

Quay accommodation for liners of 300 metres (984 feet) will shortly be completed.

Hosted by Google

The works for the improvement of this port, which were sanctioned in 1895, are being pushed rapidly forward, and are expected to be completed in about two years' time.

The new entrance, giving access from the outer harbour to the inner basin, which was opened a few months ago, is working satisfactorily. Ships requiring to enter this basin are no longer detained outside on account of the tide, as was formerly the case.

FISH-CULTURE ON A SMALL SCALE.

It is the opinion of some competent authorities on pisciculture in France, that the rearing of fish on a small scale might prove a profitable occupation if conducted on systematic principles. Many persons are inclined to imagine that this industry can be only carried on successfully in rivers, streams, or lakes. Fish-culture, like bee-keeping, and many other rural industries, may be practised to advantage even where such conditions do not obtain, and prove, in the hands of the small farmer or landowner, a source of profit and interest.

The supply of water for a small establishment need not be greater than that required for a small fountain, with a comparatively small inflow and outflow, such as is so frequently found in the gardens of country houses. Fish can be reared more profitably in small tanks than is the case where the young fry are turned out into a river or lake to shift for themselves, and where it is impossible to protect them from their many natural enemies, as well as from poachers. Where fish are reared on the "intensive" plan, that is to say, in small tanks and artificially fed, it is of the highest importance to breed only those kinds which fetch the highest prices in the market. For this reason the *Salmonidæ*, or fish of the salmon family, which includes the trout and char, are preferable to carp, tench, eels, and other coarse fish, which are better suited for rivers or ponds. The former always find a ready market in all large towns, at prices ranging from 4 francs to 5 francs per kilog. (1*s*. 6*d*. to 2*s*. per lb.), whilst the latter seldom are worth more than 1 franc to 2 francs per kilog. (4½*d*. to 9*d*. per lb.). During the close season as much as 10 francs per kilog. (4*s*. per lb.) is sometimes paid for trout in Paris.

The most suitable fish for small intensive culture are, without doubt, the rainbow trout of California (*Salmo irideus*) and the North American brook trout (*Salvelinus fontinalis*), which is really a char. Both these fish have been acclimatised in Europe. The common migratory trout (*Salmo fario*) of our European rivers does not adapt itself so well to captivity as its American kindred, which, with artificial feeding, grow very rapidly.

The American brook trout (*Salvelinus fontinalis*) appears to be particularly suitable for intensive culture, growing with great rapidity. A specimen taken out of the water, weighing 100 grammes (3½ ozs.), on January 1st last year, and weighed again five months later, had increased to 300 grammes (10½ ozs.), or three times its original weight.

The rainbow trout, as well as the brook trout, thrives better in colder water than other varieties of fish, such as the carp or tench. The temperature of the tanks ought never to be allowed to exceed 64° or 65° F. The tanks in which the fish are kept require to be well shaded, and may be established in some empty barn or suitable outhouse. The size is immaterial, but it has been found that long, narrow tanks, from 20 ft. to 30 ft. long, by 3 ft. wide and 3 ft. deep, are the most manageable size. They should be built of concrete, in pairs, above ground, so as to facilitate drainage. They should communicate with each other by a cross channel, provided with a suitable sluice. The sides and bottoms require to be well rendered with cement, in order to obtain a very smooth surface. Scrupulous cleanliness is essential in fish-culture to ensure success.

The fish require feeding three or four times a day, with slaughterhouse refuse, chopped meat, horseflesh, etc.

It is found in France that fish of about a year's growth, weighing about 100 grammes each (3½ ozs.), are the most marketable size, and this is the most profitable size to the breeder, for beyond that weight they consume, in proportion, a far greater quantity of food than the smaller fish.

OBITUARY.

Sir Raymond West, K.C.I.E.—Sir Raymond West died at his house at Norwood on the 9th inst. He was born in 1832, and joined the Indian Civil Service in 1856 as one of the first batch of successful candidates after the Service had been thrown open to competition. After holding various judicial appointments, he became, in 1871, Judge of the High Court, Bombay, and in 1887 a member of the Bombay Government. In 1892 he retired. He attained a high reputation as a jurist, and introduced many important judicial reforms. While still a member of the Indian Civil Service, he held for a time the office of Procureur-General in Egypt, and produced a valuable report, although the recommendations were of too drastic a character to be immediately adopted. After his retirement he was Reader on Indian Law to the University of Cambridge, and he held this post for fourteen years. He was knighted in 1877.

Sir Raymond became a member of the Royal Society of Arts in 1892, and has served on the committee of the Indian Section since 1893. In the year following his election (1893) he read a paper on "Agrarian Legislation for the Dekhan and its Results." He was a very frequent attendant at the meetings of the Section, and constantly took part in the discussions, the last time when he spoke here being in the discussion on Mr. Yusuf

Hosted by Google

Ali's paper on "Indian Mohammedans," in December, 1906.

SIR ROBERT PULLAR, LL.D.—Sir Robert Pullar, an old member of the Society, which he joined in 1876, died on the 9th inst. at Perth. He had for a long time been the senior partner of the well-known firm of dyers at Perth, which had been started by Sir Robert's father about 1824. It is stated in the obituary notice which appeared in the *Times* that when Dr. Perkin produced a coal-tar dye, its practical use was first demonstrated by the inventor at the Perth works in 1856. Sir Robert Pullar represented Perth from 1907 to 1910, although he was nearly eighty when he entered Parliament. He took a great interest in public affairs, and it was his services to Perth, and to charitable, philanthropic, and educational institutions in various parts of Scotland that gained him his knighthood in 1898. He was born in 1828.

NOTES ON BOOKS.

COMMERCIAL GUIDE TO THE FOREST ECONOMIC PRODUCTS OF INDIA. By R. S. Pearson, F.L.S., Economist at the Forest Research Institute, Dehra Dun; Imperial Forest Service, India; Superintendent Government Printing Office, Calcutta. Rupee 1, or 1*s.* 6*d.*

The British Government of India is one of the three most scientifically, and ably, and honestly administered in the world, the other two being those of France and Germany; and, excepting in its Educational Department, it is absolutely the most benevolently administered, even before that of France; while in no other sphere of its imperial authority and responsibilities, unless it be the Judicial, have the results of its benignant operations become so rapidly and tangibly apparent as in the Forest Department. The fact is that, owing to the destructive ravages of the Afghan invaders of Hindustan, and of the maraudings of the Mahrattas in the Deccan, and the direful depredations of the Pindharis, followed up as these were by the scarcely less desolating system of *Kumari* cultivation [that is clearing large forest spaces and burning out the trees on them, just for a year's cultivation of grain, or other staple food, and then passing on to make another clearing for the following year], India would by this time have been reduced to the same desert condition as Persia, but for the gradual settlement of the whole peninsula, between 1757 and 1857, under the paramount power of "the British Raj." Roxburgh and Wallich in Bengal were the first to draw attention to the condition of the forests of Hindustan; emulated later by Alexander Gibson in Bombay, and Henry Valentine Conolly and General Michael in Madras, and Dalzell in Sindh; but it was not until the British Association was led to take the matter up in 1850 and 1851, that forest conservancy was officially organised throughout India, and extended into Burmah; where fortunately the forests continue to flourish to the present day in something of their primeval luxuriance and grandeur. It remains to be seen to what extent the restoration of the forests of Sindh, and of Rajputana, and the Doab [the country between the "Two-waters" of the Jamna and Ganges—compare Mesopotamia], may, during the next one hundred years, affect the climate of Western and North-Western India; for "the South-West Monsoon" is markedly regulated in its date and volume by the stupendous updraught of hot air from the burning surface of these arid regions, sucking up the moisture evaporated from the Arabian Sea and pouring it down in rain over all the Bombay Presidency, and in a lesser measure on Central India and Rajputana, with occasional sprinkles over Sindh. But apart from untoward consequences, due to possible derangements of the mechanism of the South-West Monsoon, as it has been known to us from 1000 B.C., only good can result to India, in an incalculable development of its commercial natural products, by the widest possible extension of the forest area of the country. The total area of reserved and unreserved forests in India and British Burma, including the Andamans, is 243,539 square miles; of which 132,509, or over one-half, has to be credited to British Burma; and as the area of Burma is, roughly speaking, less than one-third that of India, we may judge at a glance how greatly the latter country suffered from the depredations of its secular conquerors from the North-West, out of Central Asia, until the British occupation of India finally put a stop to them. The perennial trade between the East and West had its first start,—all its fresh springs,—in the export of the commercial products of the forests, to which were later added those of the fields, and the rural looms, of India; and this trade was from the first so great and profitable that it made the greatness of all the countries through which in ancient times it took its overland course, whether through the Persian Gulf and Chaldæa, and Assyria, and Babylonia, or through the Red Sea and Egypt;—the Phœnicians first, and, after them, the Greeks, acting as its carriers among all the countries of the Mediterranean Sea. The breaking up of these routes by the Arabs and Mongols made the fame of Venice and Genoa; and on their temporary ruin, by the discovery of the open ocean high road to the East round the Cape of Good Hope, the monopoly of the trade with India, and Farther India, and the Indian Archipelago, and "Higher India" [China and Japan] fell in succession into the hands of the Portuguese, the Dutch, and the English. It was because the Dutch raised the price of pepper against us that we formed, in the reign of Queen Elizabeth, our first East India Company; and the first dredge of English-borne pepper from the East was as the womb of the birth of our whole Indian Empire in the consolidated form it took during the reign of Queen Victoria. But on Ferdinand de Lesseps opening the Suez Canal, which we had all

Hosted by Google

along bitterly opposed, Italy was the first to profit by the reopening of the Overland Route to India through Egypt; until to-day both Venice, "throned on her hundred isles," and Genoa bid fair to recover their mediæval commercial glories; and Egypt more than its ancient position of commercial and political command between the Mediterranean and the Red Seas. The advantage of France, by whom it is gradually being seized, is in her having a frontage both on the Mediterranean and on the Atlantic; for, fundamentally, the nations are but so many shops, and oceans and rivers the highways and byways of their traffics: and unless they are doing a good business as shopkeepers, their armies, and navies, and diplomacies, all their seeming power and pomp, are but vanity of vanities. It is difficult to overestimate the antiquity of the trade in the commercial products of the forests, and fields, and gardens of India, and Burma, "the Earth's Green End" of Homer. Weber placed it at 1600 B.C. It would seem to have been regularly organised by 1000 B.C.; and it is certain that from the most ancient historical times the people of India themselves, in co-operation with the Sabæans and Minæans of Arabia, took a part in its development. The name of the island of Socotra is said to be Sanskrit; and the Greek for tin, which gives its name to the Cassiterides, or "Tin [export] islands" off the coast of Cornwall is Sanskrit; and our word "sugar" is unmodified Sanskrit. The Havilah of Genesis ii. 11-12, may not mean India [although I am, myself, convinced it does], but "bdellium" [*bdolach*], mentioned as one of the products of Havilah, whether it refers to bdellium, or to musk, is, in either case, an Indian product; and the word itself is the Sanskrit *madalaka*, the μαδελκον, and μαλαχη of the Greeks, and *mukul* of the Hindus of to-day, and *molochil* and *mukul* of the Arabs. The actual name of India occurs in Esther i. 1, and viii. 9, in the Hebrew form of *Hoddu*, in Syriac *Hendu*, and in Arabic *Hind;* and where, in ch. i. 6, of our "Authorised Version," the Bible, has "white, green, and blue curtains," it should read "white and blue (striped) cotton curtains," that is the cheap cotton rugs made all over India, and used also as "beds" and hangings; —the Hebrew word translated [A.V.] "green" being *Karpas*, which is simply the Sanskrit *Karpasa*, cotton, an aboriginal Indian forest and agricultural product. The Hebrew *sadin* for (calico) "sheets," "fine linen," etc. [Judges xiv. 12-13, Proverbs xxxi. 24, and Isaiah iii. 23], and the Greek σινδων, represent the most ancient Sanskrit name of India [first applied to the valley of the Indus], Sindhu; which in Persian and Arabic became, Hindu, and Hind; and in Greek and Roman India. And so on, and so on, with a hundred Indian mineral, and vegetable, and animal products that have been renowned throughout Europe from the times of Homer, and Hippocrates, and Herodotus, and Pliny, and Dioscorides, and Athenæus;—as fully set forth by me in the "Handbook to the British Indian Section of the Paris Universal Exhibition of 1878."

As to the uses to which timbers and subsidiary forest products, such as tans, dyes, drugs, etc., etc., can be put, exhaustive information is given in Gamble's "Manual of Indian Timbers," Sir Dietrich Brandis's "Forest Trees of North Western and Central India," and in Sir George Watts's colossal work on "The Commercial Products of India"; but the special purpose of Mr. Pearson's present report—and it has been perfectly fulfilled—is to give all that is known of these major and minor Indian forest products in a form, and with the particular details, required by English manufacturers, and the general dealers in, and the importers of, these economic articles; and this is thoroughly well done in 171 pages, divided into three chapters.

The first chapter, after a page or two on the institution of Forest Conservancy by the Government of India, and the distribution of the forest areas of India and Burma, treats of the different types of Indian forests, the Deodar ["God's tree," *cf.* Numbers xxiv. 6] Forests of the Himalayas, the Bamboo Forests of Arakan, the *Acacia arabica* Forests of Sindh, Rajputana, Gujarat, and Central India; the Teak Forests of Bombay, the Evergreen Forests [of Strychnine, and Mango trees, etc.] of the Malabar Coast, the Catechu Forests of the Canara Country, the Tidal Forests [of Mangroves] at the deltas of all the greater rivers of peninsular India, etc., sixteen types in all; the annual output of the whole amounting, in 1907-08, to 4,699,642 tons, of the value of Rs. 26,000,000. It is worth mentioning here how I observed in the Strychnine districts about Bombay, that the Indian children who eat of its divinely painted fruit, swallowed "the stones" with it, without any sort of injury to themselves, —to which fact every road side along my way bore indisputable evidence. The Hornbills, apparently, crunched the seeds up before swallowing them!

The second chapter gives the fullest economic information of eighty of the chief forest trees of India, their timbers, and their subsidiary products; and tells you, in each instance, where inquiries should be made regarding them.

The third chapter is concerned wholly with the minor forest products; such as (1) fibres and leaves, and basts and flosses [such as the silky *Kapock* of *Cochlospermum Gossypium*, the Silk-Cotton Tree, and of the herbaceous shrub *Calotropis gigantea*]; (2) grasses for fibres, and thatchings, and grazing; (3) distillation products, such as *rosha* oil, lemon-grass oil, sandal-wood oil, *Agar-Agar* oil, Cinnamon oil, "*Mohwa* liquor," etc.; (4) oil seeds; (5) dyes and tans; (6) gums and resin; (7) rubber; (8) drugs and spices; (9) fruits and edible seeds; (10) "bamboos" and canes; (11) animal products, such as lac, wax, honey, etc.; and (12) mineral products: and the volume closes with two most helpful indexes, one of the scientific botanical names of trees, shrubs, and other plants mentioned

Hosted by Google

in it, and the other of their vernacular names, with the equivalent scientific names, opposite them.

It is needless to say that a book of this character by Mr. Pearson, and bearing the imprimatur of the Government of India, is beyond all praise by me. It has no sins of commission, and its only sin of omission is probably to its official credit. He avoids all reference to the ancient history of the commercial products with which he deals; but the highest interest in them is not in their sordid utility to ourselves, but in their having been known and useful to Babylon, and Nineveh, and Egypt, and Israel, and Greece, and Rome; this fact, as I have personally observed, tending to arouse even in the hard-headed industrial and commercial dealers in them a nobler fervour in their own specialised avocations; and surely the Government likewise would directly gain if, in the preparation of such publications, they made them attractive also to the student of Indian history, and even to the general reader. The neglect of the historical method, moreover, often does the most painful injustice, quite unintentionally, to the men who have gone before us in the field of our own labours. Thus, in his first chapter, Mr. Pearson writes:—"The first serious attempts to increase the area [in the Madras Presidency] under teak were made some eighty years ago by a Civilian, *of the name of Conolly*";—[the italics are mine own!]. Now this was Henry Valentine Conolly, of the Madras Civil Service, and a "Member of Council," Madras, one of the pioneers of forest conservancy in India, assassinated by the Moplas in 1855; and the eldest of four brothers, all of whose names are as household words among Anglo-Indians of the days of the Honourable East India Company; the three others being Arthur Conolly, of the Bengal Cavalry, the author of a work in two volumes [London, 1834] on his overland journey through Persia and Afghanistan to India, and murdered along with Stoddart in prison at Bokhara, 1841–2; Edward Conolly, of the Bengal Cavalry, Commandant of Macnaughten's escort at Cabul, and killed at Purwan Durrah, fighting under Sale in 1840; and Captain John Conolly, killed at the capture of Cabul, 1842. All four brothers died violent deaths in the service of their country; and yet the most distinguished of them all, and one of the founders of the Indian Forest Department, is written of in Mr. Pearson's Report as:—"a Civilian of the name of Conolly." But the fault of it is in no way that of Mr. Pearson, but of the system under which such official works are devised, determined, and done: and except for this default Mr. Pearson and the Government of India alike are to be most gratefully congratulated for this "Commercial Guide to the Forest Economic Products of India." I have dwelt on the default simply because the full, the overflowing recognition of the services of our predecessors in science, art and literature, is of the very foundation of personal, and commercial, and national "culture."

George Birdwood.

GENERAL NOTES.

The Use of Motor-power for Fishing-boats in Japan.—Since the Japanese deep-sea fishing encouragement law was enacted (1910), motor-power has been employed to a great extent for fishing-boats. There are at present about six hundred fishing-boats worked by motor-power and forty-one trawl steamers. Trawl fishing, which was not introduced into Japan until 1907, has been especially successful, and it is thought that in a short time there will be eighty of these boats engaged in the fishing industry on the coasts. Several trawlers are being built at the Osaka Iron Works and other yards, while some have been recently purchased in England at an estimated cost, according to the American Consul at Kobe, of £6,000 each. These steamers are beam trawlers, they run about 150 tons gross, and are built in the same general style, size, and fittings as the trawlers used on the east coast of England. Their fittings, such as winches, many of their nets, and other gear are imported from England, while the boilers and engines are constructed in Japan. The boats are manned by from forty to sixty men, according to their size. They return a profit of ten to twenty per cent. per annum on the investment, as there is always a large market for fish in Japan, the Japanese being great fish eaters. The annual value of fish supplied by the Kobe fish market is given as £300,000, while the fish supplied to Kioto and the neighbourhood from the Kobe market is valued at £150,000. This does not include Osaka, a city of 1,250,000 inhabitants. All edible fish, such as codfish, tai, sea-trout, sole, and many others, are selected for the market, while the non-edible varieties are used for fertilisers after the oil is extracted. Where trawlers work, the bottom must be free from rock and large boulders, otherwise the damage to the nets and gear would diminish the profit considerably.

The Preparation of Bitter Oranges in Valencia.—The oranges canned in Valencia for use in the manufacture of marmalade are exclusively the bitter oranges grown in that district, supplemented occasionally by supplies of the same variety brought from Seville. The operation of canning is as follows, each of the steps being performed by a different set of workers. The oranges are immersed in hot water for a few moments and cleaned with a stiff brush; they are cut in half perpendicularly to their axes; the interior is scooped out of the skins with a chisel-shaped wooden implement some eight or ten inches long by one inch wide. The seeds are then picked from the pulp by hand, and the latter is put in cauldrons where it is boiled by itself for half an hour. It is then passed through a macerating machine, when it is ready to be mixed with the shredded peel and canned. The skins, after the pulp has been removed from them, are placed in a machine which cuts them into long thin shreds.

Hosted by Google

These shreds are boiled by themselves for forty-five minutes, when they are ready to be mixed with the pulp and canned. The pulp and shredded peel are canned together in their original proportions—that is to say, the skin of one orange is considered in Valencia the proper amount to balance the pulp of one orange in the finished product, though British preserving houses frequently add extra pulp, which they obtain chiefly from manufacturers of essential oils and flavouring extracts, who use only peel for those purposes. The cans are sealed and then boiled for ten minutes, when the process is complete.

THE CASSAVA INDUSTRY IN JAMAICA.—Cassava, which is also known as "Manioc," a corruption of the name of the genus "Manihot," is cultivated extensively in the West Indies, in South America, and in Africa, where it forms a staple article of diet. In Jamaica cassava ranks third among the "ground provisions," which are the principal articles of food among the natives, yams coming first, and potatoes second. Both kinds of cassava are grown in Jamaica, the sweet cassava (*Manihot aipi*) and the bitter cassava (*Manihot utilissima*) both being prolific bearers of farinaceous tubers, usually eight to ten inches in length and one to three inches in diameter. The tubers of the sweet cassava are eaten as a vegetable, like yams and potatoes. The bitter cassava contains an acrid, poisonous, milky juice, which has to be removed by pressure after the tubers have been washed, scraped, and grated. Bitter cassava is extensively used to make starch for local use and in making "bammies," a sort of cake much used as a substitute for bread in the southern and western parts of the island. Cassava wafers are regarded as a great delicacy by tourists in Jamaica.

MINERAL OUTPUT OF THE UNITED KINGDOM.—According to the report of the Chief Inspector of Mines, just published [Cd. 6340], the total number of persons employed in and about the mines of the United Kingdom in 1911 was 1,096,238, an increase of 18,155 as compared with the figures for 1910. Of the 203,701 surface workers, 6,279, or 3·08 per cent., were females. This is an increase of 58 females as compared with the previous year. The total output of minerals at the mines under the Coal Mines Act was 285,942,232 tons, of which 271,878,124 were coal, 2,482,846 fireclay, 7,886,898 ironstone, 3,116,803 oil-shale, and 577,561 sundry minerals. With the addition of 13,775 tons from open quarries, the total output of coal was 271,891,899 tons, an increase of 7,458,871 tons on the total for 1910, and the greatest output yet recorded.

MATERIALS FOR PAPER-MAKING IN VENEZUELA.—One of the principal articles used in paper-making in Venezuela is the "gamelote" grass (*Panicum myurus*), a broad-leaf grass of very bountiful growth in the tropical sections of Central and South America. In addition to the gamelote used, there are many other grasses, rushes, trees, and plants growing naturally in Venezuela that can be used in the manufacture of paper pulp, among which should be specially mentioned the tree known as the "majagua," or *Paritium tiliaceum*, the wood of which is very much like that of the western cottonwood. This tree is of rapid growth in its usual habitat at an elevation of 2,500 to 4,000 feet, and is easily planted. In Central America it is used a great deal for shade on coffee plantations. It has a broad leaf, but the limbs and leaves are sufficiently far apart to permit the sun to reach the ground beneath, although in such a manner that the rays are broken, and the ground is not baked by them. The inner bark of this tree has a long fibre, which is used in Central America for making rope.

THE TURKISH COTTON INDUSTRY.—The cotton-growing industry of Turkey, which acquired some importance during the American Civil War and declined shortly thereafter, is reviving. In the Cilician Plain, 85,000 bales were produced in 1911. Of these, 50,000 were exported to Austria, Spain, Italy, Germany and France, the estimated value being nearly £450,000. In the Smyrna district 40,000 bales were produced in 1911, of which 28,000 were shipped abroad. Turkey is beginning to manufacture cotton goods, and will require an increasing percentage of its raw cotton for home consumption, while finer, long-fibre qualities may be needed from the United States. Besides spinning-mills at Adana and Tarsus, a British firm has a cloth factory in Smyrna for the manufacture of "cabot" for the Ottoman army. Cotton-growing is expected to make great strides in Turkey, especially in the lowlands of the Jordan, the Tigris, and other rivers emptying into the Mediterranean Sea and the Persian Gulf.

THE AGRICULTURAL PRODUCTS OF THE BELGIAN CONGO.—The wild natural products of the tropical soil have always been a source of great wealth to the Congo. Of these, rubber easily takes the leading place, and millions of rubber trees of different kinds have been planted. The oil palm stands next in importance to rubber from the export standpoint, and is of much greater value to the native population. It furnishes them with food, drink, building material, and wealth. The oils obtained from the fleshy portion of the palm nut and the crushed kernel are exported by tons for soap-making and other purposes. In modern agriculture there has been little progress. Experiments have been made in growing cocoa, coffee, rice, pineapples and maize. The greatest success has been obtained with cocoa, which thrives in the fertile valleys of the Mayumbe. The species of cocoa planted is the "amenolado," from the island of San Thome. As regards pineapples, the "smooth cayenne" variety from the Azores grows well, and can be shipped fresh to Europe in cold storage. An excellent quality of native pineapple grows wild, and is utilised by the missionaries. Bananas, oranges, mangoes, pawpaws, and many other native fruits flourish if given a little care.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

THE LOOM AND SPINDLE: PAST, PRESENT AND FUTURE.*

By Luther Hooper.

Lecture III.—Delivered March 11th, 1912.

Introduction.

Those of you who have attended the two previous lectures of the course will have realised that my chief aim has been to point out the traditional continuity of the art of weaving, and to show that all real advances in it have been made by bringing new ideas to bear on old principles. This method of advance is common not only to the textile but to all the arts of life. Man, at his best, is not a creator, but an improver, and all attempts to break with tradition and to produce something quite original always must end in more or less grotesque failure.

I have tried to bring this truth out as regards the hand-loom and spindle, and to-night I shall chiefly direct your attention to the same fact, as exemplified in the development of the mechanism of the power-loom during the last century.

The Modern Loom for Plain and Ornamental Weaving and its Future Development.

In the early part of the eighteenth century, weaving, as a handicraft, reached in Europe its point of highest perfection. France, England, and Italy were the chief countries in which it was practised.

At that time, in England particularly, the condition of the textile craftsman, of whatever grade, seems to have been better than at any other period of which we have record.

The weaver of the eighteenth century was a prosperous and respectable tradesman, whether working in the secluded country village, in the suburbs of the great towns of the north and east, or near the metropolis in the pleasant district of Spitalfields—notable as the silk-weaving quarter of London.

This happy condition of the weaver in the eighteenth century declined to one of misery in the nineteenth. The economic causes of this change are not far to seek, but form no part of my subject. I only refer to this period of prosperity, as it marks an important stage and change of direction in the development of the loom.

Hitherto the motive of inventors was to increase the scope and perfection of the loom as a pattern-weaving tool. The perfection attained and the care bestowed on loom construction are shown in the beautiful illustrations of Diderot's Dictionary and other technical works of the period.

During the latter portion of the eighteenth century, and since, the chief purpose of invention has been, not excellence of work and extended capacity of the loom, but economy of time and cheapening of production.

The interesting business of weaving, from the tying-up of the design to the picking and finishing of the woven cloth, which the weaver originally did himself, is now divided up amongst half a dozen "hands," who only do one particular portion of the work, and thus monotonously perform their daily task.

Not only is the weaver's work to a certain extent degraded, but the change from wood to iron for loom construction, and the use of steam as a motive power, as well as the subdivision of labour, have necessitated the grouping of looms in large factories, with all their inconveniences and attendant evils.

This revolution of industry occupied more than a century and a half, and was effected in some branches of the trade sooner than in others. The process is, in fact, in the best branches of silk weaving, still going on.

* A large number of the illustrations are taken from Mr. Hooper's "Hand-Loom Weaving," and are reproduced by the courtesy of the publisher, Mr. John Hogg.

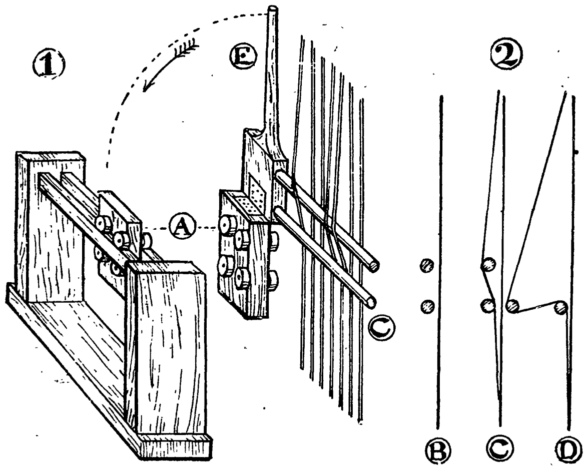

FIG. 46.—DRAW-BOY'S FORK.

The first indication of the coming change in the broad-weaving trade was given as early as 1687, when Joseph Mason patented a machine which he described as "an engine by the help of which a weaver may performe the whole work of weaving such stuffe as the greate weaving trade of Norwich doth now depend on, without the help of a draught-boy, which engine hath been tryed and found out to be of greate use to the said weaving trade."

It is necessary to the understanding of the mechanism of the important machine which superseded it, which I shall presently fully describe, to have a general idea of this draw-boy machine. In order to give this idea, however, I must first describe the work of the human draw-boy. For this purpose we shall need the diagram of the draw-loom used last week (Fig. 44).

[Here the lecturer again briefly repeated his explanation of the various parts of the draw-loom.]

In a rich silk loom there were often as many as two or three thousand lead weights, called *lingoes*, hanging three to each leash of the monture. These weigh altogether a couple of hundredweight. On an average half of them had to be drawn up at every line of the design. Moreover, their *dead weight* would be so increased by the friction of the multitude of cords and pulleys that the boy would have to raise and hold, for several seconds, a weight equal to a hundredweight and a half. This would, of course, be impossible but for some mechanical help. The implement devised for the boy's assistance was called the "draw-boy's fork." This is shown at Fig. 46.

The vertical lines in this diagram represent the cords of the simple.

To the left is a solid stand, having two broad uprights joined together at the top by two parallel bars. A is a block of hard wood, which fits between the bars, and is held in position by four pairs of small wheels. These not only support it but allow it to run freely from end to end of the stand.

This block, with the fork and lever attached, is shown separately at E. The fork and lever are hinged to the block at its top, and can be moved from the vertical to a horizontal position. When about to be used the block is moved till the points of the fork are just beyond the backmost cord of the simple, the lever being in an upright position.

By means of the loops tied to the simple, as shown at Fig. 46, the required cords are drawn forward, and the upper prong of the fork inserted in the opening thus made. Then, grasping the lever, the boy draws it down and holds it. The result of this is that the selected lingoes and leashes are drawn and held up.

At No. 2 three sections of the simple are

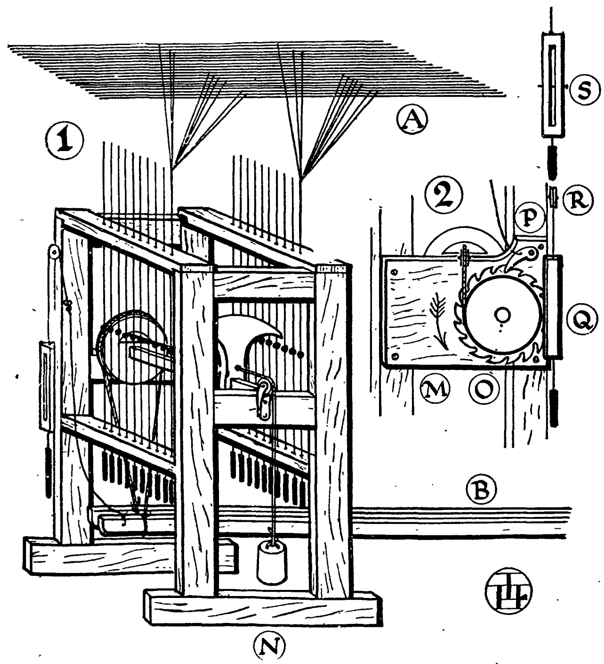

FIG. 47.—THE MECHANICAL DRAW-BOY.

shown, lettered B, C, and D. At B the cords are at rest. At C some cords have been selected and the fork inserted. At D the lever has been pulled over and the cords drawn over with it.

Fig. 47 shows the mechanical draw-boy, a machine invented in the seventeenth century, and improved during the eighteenth. It was attached to the pulley-cords of the loom, on which, when the machine was used, the tie-up of the design was made, instead of on the simple.

The active part of this machine is the pecker, which, by means of two treadles and some little mechanical arrangements, had two movements: (1) it rocked from side to side; (2) it moved, as it rocked, along the machine from one end to the other.

Through holes, in the side cross-pieces of the frame, strong cords terminating in heavy weights, were hung. To the tops of these cords the loops of each row of tie-ups were attached in regular succession. Only two rows are shown connected in the diagram to prevent confusion of lines.

The pecker had a deep notch cut in its points, and was of such a size that, as it rocked, the cord towards which it inclined caught in the notch. At the centre of the cord a large bead was fixed. When the rocking pecker came in contact with this bead it pushed it and its cord down, and held it until the second treadle moved the pecker in the opposite direction.

As the pecker travelled along the shaft each cord was drawn down in its turn, thus opening the shed, line by line, for the working out of the pattern.

The number of lines in the length of a design of course had to correspond with the number of cords in the machine. The draw-boy machine was not, to any great extent, used for the purpose for which it was intended—viz., to supersede the draw-boy of the compound figure weaving loom. I suspect the boy was useful in many ways about the loom, and, moreover, his wages would be no great matter. But late in the eighteenth century, and well into the nineteenth, the machine received a good deal of attention, and was improved and adapted for use with the treadle hand-loom. It enabled the weaver to work any complicated system of heddles, for small pattern fancy weaving, with only two treadles instead of twenty or more.

Fig. 48 is from Porter's Treatise on Silk (1831). It represents an improved draw-boy machine, for which the Society of Arts awarded a prize in 1807. Further improvements were made later, but it was finally superseded by the famous machine which was perfected by Joseph Marie Jacquard, and known in England as the "Jackard" machine.

There can be no doubt that it is to Jacquard that the credit of rendering this machine thoroughly practical is due, although it has been proved that the fundamental idea of it, which consists in substituting for the weaver's tie-up a band of perforated paper, was first applied to the draw-loom in 1725, while in 1728 a chain of cards was substituted for the paper and a perforated cylinder also added.

These early contrivances were placed by the side of the loom and worked by an assistant. In 1745 Vaucanson placed the apparatus at the top of the loom and made the cylinder rotate automatically. But it was reserved for

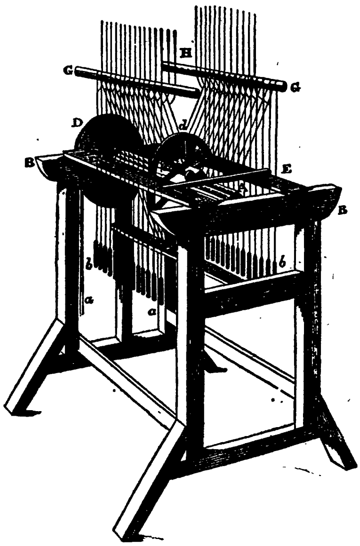

FIG. 48.—THE MECHANICAL DRAW-BOY.
(Early Nineteenth Century.)

Jacquard to carry the machine to such perfection that, although many slight improvements have since been made in it, it remains to-day practically the same as he introduced it in 1801, notwithstanding the astonishing development of textile machinery during the nineteenth century, and the universal adoption of the machine both for hand and power weaving.

Although the invention was introduced to the French public in 1801, it was not till 1820 that a few Jacquard machines were smuggled into England and secretly set up. In spite of much opposition, they soon came into general use, first, and particularly, for hand-looms and silk weaving, but afterwards for power-looms, all kinds of fancy and ornamental webs being, since their adoption, woven by their means.

Hosted by Google

May I here repeat and emphasise that the invention of the Jacquard machine did not alter in the least the draw-loom method of pattern

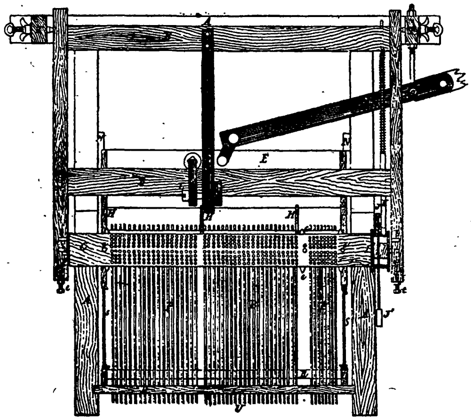

Fig. 49.—Jacquard Machine.
(Front elevation.)

weaving. It only took the place of the draw-boy and the pulley-box; and substituted the endless band of perforated cards for the weaver's tie-up.

The designs, too, draughted on ruled paper, would be worked out in precisely the same manner, whether for tying-up on the cords of a simple, or for punching in a set of Jacquard cards. *Each card, in fact, takes the place of one row of loops of the tie-up.*

The term Jacquard weaving, then, which one so often hears used, is a misnomer. It should be draw-loom weaving with a Jacquard machine, the machine being only an ingenious substitute for a less compact and manageable adjunct of the draw-loom, an adjunct, moreover, which, as we have seen, has continually varied from the time of the invention of this form of loom. After the draw-loom itself, I should class the Jacquard machine as the most important invention in textile mechanism. It therefore claims a careful description.

Fig. 49 is a drawing of the front elevation of a 400 Jacquard machine. The number 400 refers to the number of needles and hooks with which the machine is fitted up. These needles and hooks answer to the number of the simple cords of the draw-loom. A design is still technically spoken of as being draughted for so many cords.

The position of the machine in the loom is at the top, where it is fixed on a solid frame just over the comber board, usually with its end to the front of the loom, so that the elevation shown in the figure is parallel with the side of the loom frame.

The machine frame is oblong in shape. It is made of hard wood for hand-looms and of iron for power-looms. But in either case it needs to be of great strength. To the principal frame a smaller one is hinged at the top, so that it can be raised like a flap.

In this drawing fifty wire hooks are seen standing upright on the bottom board of the machine. The bottom board is perforated with as many holes as there are hooks in the machine, in this case 400. The hooks represented are only one rank, out of eight, which the machine contains. Each hole in the bottom board has a dent or groove cut across the top, in which the bent end of the wire hook rests. This keeps the hook firmly in position, especially when the necking cords of the harness are brought up through the holes and looped on to the wire.

Fig. 50 gives two sections of the machine, one showing it at rest and the other showing it in action. In both sections eight hooks are drawn, one from each rank of fifty.

The hooks have the necking cords attached at the lower ends, and just below the small hook at the top may be seen a set of eight wires, crossing them at right angles. Each of these wires—called needles—is bent into a loop, or eye, where it crosses one of the hooks, and it is because the hook is passed through this eye that it is retained in an upright position. Fig. 51 will show this arrangement quite clearly.

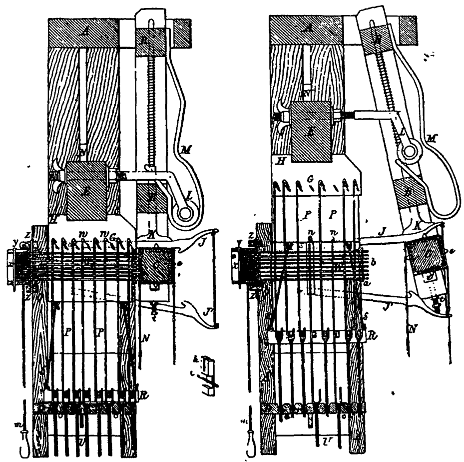

Fig. 50.—Sections of Jacquard Machine.

Each hook thus resting on the bottom board, and held down by the weight of the leashes of the harness, though supported at the top by the eye of the needle, through which it passes,

Hosted by Google

is still free to rise and raise with it the leash or leashes to which it is attached.

Leaving the hooks thus standing, let us consider the arrangement for lifting them.

Above the hooks the section of a solid block of heavy wood or iron is shown. This block runs from end to end of the machine, and has projections at its ends which fit into the narrow spaces between the two pairs of uprights of the machine frame in such a manner that the block can be caused to slide up and down steadily but freely.

Now let us look at the block in the drawing of the front elevation (Fig. 49), and then at a drawing showing the block in detail, separately.

The lever for raising the block being extended to a convenient length, is connected by a rope to a treadle worked by the weaver's foot in the hand-loom, or by any ordinary mechanical arrangement in the power-loom.

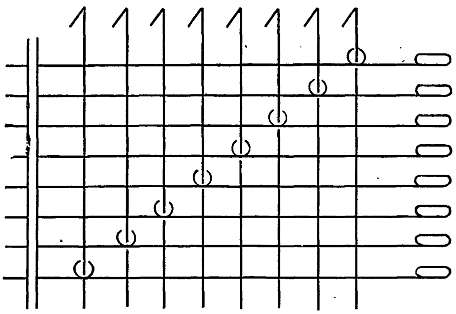

FIG. 51.—DIAGRAM OF HOOKS AND NEEDLES IN A JACQUARD MACHINE.

Fig. 52 gives us details of the block: (1) as seen in front elevation; (2) from above; and (3) from the end.

The block, the lever, and the arrangements for sliding up and down are already explained. But hanging from the block is a kind of gridiron, called by the weaver a "griffe," which requires careful notice. Near each end of the block a flat plate of iron is firmly fixed. The shape of the plate is shown at No. 3, and between the plates, eight bars of hoop iron are fitted, as at No. 2. These bars are placed diagonally (see No. 3), and their top edges are sharpened so as to fit under the carefully-made small hooks at the top ends of the upright wires as they stand in their several rows.

The first section of Fig. 50 shows the block at its lowest position, with the hooks caught on the bars of the griffe. Should the block now be raised, the whole of the 400 hooks will be drawn up and the whole warp will rise with them. When released, of course, all will fall together, pulled down by the lead weights. Again, if the projecting ends of the needles are pushed inwards, the needle eyes will deflect the hooks, and remove them from the griffe, which will then, if the block be raised, rise by itself, leaving the hooks, leashes, and warp all down, as in section 2.

In section 2 the points of the needles are seen to pass through and project beyond the surface of an accurately perforated board fixed to the front of the machine frame opposite the needles. Hung in the frame, hinged to the top of the machine, is a four-sided revolving bar, or cylinder, each side being perforated so as to match exactly the perforations of the needle board.

If the flap, with the cylinder in it, be pressed against the board, and the block raised, nothing different will happen, because the points of the needles will have been free to enter the holes in

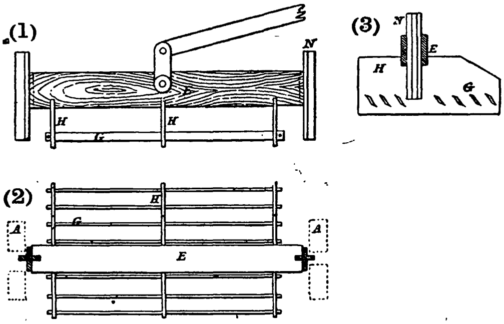

FIG. 52.—DETAILS OF THE BLOCK OF A JACQUARD MACHINE.

the cylinder. If, however, a card covering all the holes be fixed to one side of the cylinder and the cylinder then be brought close up, presenting each side in regular succession, every time the card comes in contact with the needle-points the needles will be pressed inwards, push the hooks off the bars of the griffe, and the block will rise without them.

It follows, then, that if we interpose between the needle-points and the side of the cylinder, as it presses the needle-board, a card perforated according to an arranged design, wherever a hole is covered by the card a needle will be pressed in, and consequently a hook will be pushed off the griffe-bar, and left down as the block rises.

Each card, therefore, affects, in one way or another, every hook in the machine with its necking cords and leashes; and these, of course determine the rising or remaining down of every thread of the warp from edge to edge of the web.

Hosted by Google

At the back of the machine a shallow box is fitted, containing four hundred small spiral springs, one for each needle. When, therefore, any needle is pressed inwards by the card on the cylinder, its opposite end is forced into the spring box, but as soon as the pressure is relaxed the needle, driven back by the spring, regains its normal position, holding the hook upright.

The mechanical contrivances by means of which the cylinder is moved, pressed against the needle-board and rotated as the block rises and descends, are most ingenious, and subject to a great deal of variation. They are, however, not essential to the principles of the machine and can be passed over. But the method by which the perforated cards are adjusted to the cylinder and interpose between it and the needle-board must be explained.

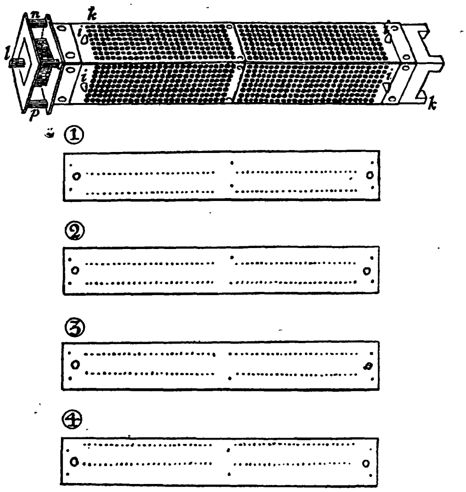

FIG. 53.—JACQUARD CYLINDER AND CARDS.

Fig. 53 shows a detached cylinder and four cards punched with a pattern called a four-lined twill. This pattern repeats on every four lines; accordingly only four cards are needed to weave it. At the ends of the cylinder, close to the perforations, pegs are fixed and holes matching these pegs in size and position are punched in the cards. These pegs hold the card in its proper place, so that its perforations correspond exactly with those of the cylinder.

Each side of the cylinder as it rotates, being covered with a card held close to it by two elastic bands, will press against a different set of needles at each of its four movements. The fifth movement, of course, brings the first set of needles again into play. When, however, as is generally the case, more than four lines of design are required, the cards have to be laced together in an endless band hung upon a rack at the side of the loom, and carried round the cylinder.

The most striking advantage of the use of the Jacquard machine in the textile arts is the facility it gives for a frequent change of design. It is only necessary to take down one set of cards and hang up another in order to change the pattern. The result of this facility was that the early part of the nineteenth century witnessed a perfect orgie of fantastic ornamentation. The manufacturers, of all sorts of ornamental silk and fine woollen textiles, vied with each other in the number and originality of the designs they could produce. The profession of designer may almost be said to be an outcome of the invention of Jacquard. Previously to this time the master weaver, or some person in practical touch with the looms, had arranged the design, and when once tied up on the loom it was good for a lifetime. But with the introduction of the new *draw-engine*, as the machine was called, all this was altered, and restless change of pattern and fashion was the result.

At first the machine was only adopted in the silk trade for the weaving of rich brocades and other elaborate materials for dress or furniture, but ever since its introduction its use has been gradually extending, all kinds of plain and ornamental textiles being now made by its means, whether on hand or power-looms.

As a work of mechanism it is truly wonderful. It can be made to govern all the operations of the loom except throwing the shuttle and actuating the lever by which it itself works. It opens the shed for the pattern, however complicated, regulates the length of the design, changes the shuttle-boxes in proper succession, rings a bell when certain points in a design requiring special treatment are reached, regulates the take-up of the woven cloth on the front roller, and works out many other details, all by means of a few holes punched in a set of cards. Its great defects are the dreadful noise it makes, the ease with which it gets out of order, and the difficulty of putting it right. These render it only suitable for factory use, where noise does not seem to matter, and where a machinist is constantly at hand to keep the mechanism in good order.

So far I have traced the development of the hand-loom, from its most primitive form to one of a high degree of perfection, as a tool for the skilful artificer. Here I must at present leave it, and turn to a brief consideration of the machine-loom actuated by steam or other power.

In order to find the earliest recorded attempt to weave by power, we must carry our imagi-

Hosted by Google

nation back to the latter part of the sixteenth century, and look in on the Fathers of the City of Dantzic, in council chamber solemnly assembled. They are deciding the fate of a prisoner accused and found guilty of the crime of inventing a very ingenious machine for weaving narrow tape several breadths at a time.

The council, having carefully considered the machine, and bearing in mind the state of the trade, were "afraid that by this invention a great many workmen might be reduced to beggary." *They, therefore, mercifully ordered the machine to be suppressed, and the inventor of it to be privately strangled or drowned!*

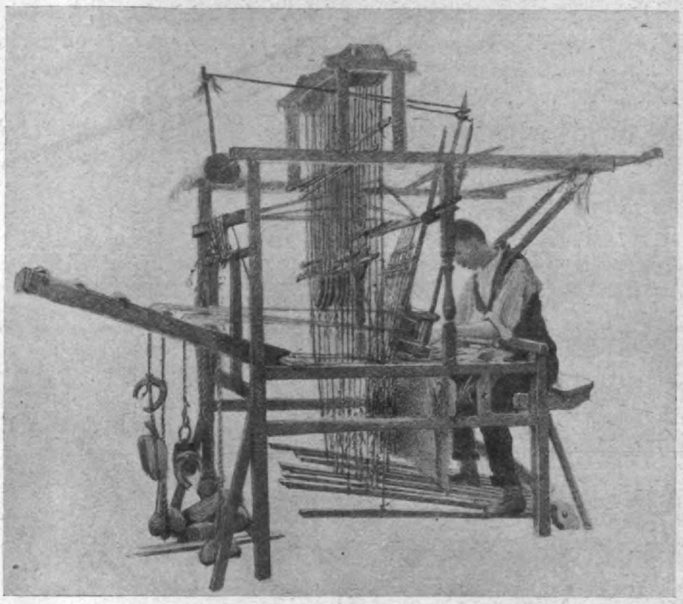

FIG. 54.—NARROW SILK WEAVER AT WORK.
(From a Drawing by the Author.)

The weaving trade has always been divided into two great branches. The broad weavers made stuffs, for garments and furniture, seldom less than twenty-one inches wide. The narrow-branch weavers made ribbons, laces, tapes, braids, galloons, and suchlike goods, and, of course, when these were only woven in single widths on hand-looms vast numbers of persons were employed in weaving them. There was a great demand for such goods in the Middle Ages.

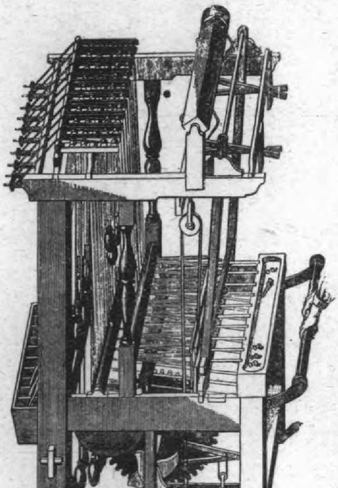

FIG. 55.—DUTCH BAR-LOOM.

Fig. 54 shows a narrow weaver at work on a hand-loom. I discovered him the other day in a small trimming factory near Piccadilly Circus. The loom he is working at is an actual survival of the eighteenth century. There are several others in use at the same factory, where braids and trimmings for high-class furniture are always being made.

Attempts were made at various times in the seventeenth century to introduce the machine tape-loom, but complaints and rioting prevented them succeeding. It was not until the eighteenth century that prohibitions were finally revoked, and the Dutch bar-loom, as it was called, came into general use.

An illustration of this loom is given in the great French mechanical encyclopædia published in 1786. It is reproduced in Fig. 55.

The reason why the ribbon-loom was so readily made workable by power was because it did not require the one movement which has always been the great obstacle in the way of weaving broad webs on machine-looms. That is, the *throw of the shuttle.* Nay, not so much the *throw*, but the *catch* of the shuttle.

Fig. 56 shows the graceful operation on which good weaving depends; an operation

Hosted by Google

which has never yet been successfully imitated by machinery, and probably never will be.

The operations of the loom in weaving are four in number: To open the shed, to throw

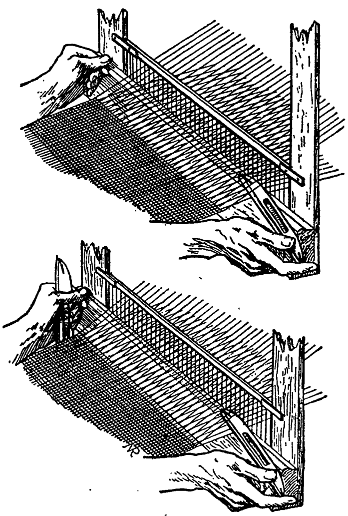

FIG. 56.—HAND SHUTTLING.

and catch the shuttle, to beat the weft together, and to wind up the woven cloth. All these, except the second, are comparatively easy to arrange for, even in broad weaving, by means of a power-driven turning shaft, furnished with cranks and eccentrics, fitted up in some convenient position in the loom. In narrow weaving the spaces of warp are so small that the passing through of the several shuttles presents no difficulty; consequently the invention of a practical automatic machine-loom for narrow weaving was an early one.

Many attempts were made in the seventeenth and early part of the eighteenth century to weave broad webs by power, but they all failed to solve the problem of the shuttle. It has been partially overcome since, but the great defect of the machine-loom to-day is in the driving and catching of the shuttle.

The invention which partially solved the difficulty, and eventually rendered the machine-loom practicable, was the fly-shuttle, intended by John Kay, its inventor, for use on the hand-loom. Its purpose was to enable a weaver to weave, without the aid of an assistant, wider webs than he could manipulate with the hand-shuttle.

Fig. 57 represents the batton used for the fly-shuttle, and should be compared with the hand-shuttle batton (Fig. 30).

The difference between hand-shuttling and fly-shuttling can almost be distinguished by comparing the two shuttles used. The hand-shuttle is slightly curved and adapted nicely to the position of the weaver's fingers. The fly-shuttle, on the contrary, is rigidly straight, so that it flies along in front of the reed, without any bias, from one end of the race to the other.

Comparing the battons, it is seen that the race-block of the fly-shuttle batton is elongated at the ends. On these ends the shuttle can stand clear of the cloth which is being woven, and which is, of course, never wider than the reed.

These elongated ends have a bar of wood so fixed in the front that there is just room for the shuttle to run in and rest between it and the back of the shuttle-box, as the elongated end is called.

Above the shuttle there is a thin, smooth iron bar, and on this the driver (enlarged at F), made of tough leather, is fitted so that it will easily slip from end to end of the box. Both boxes are furnished with drivers and are fitted up in exactly

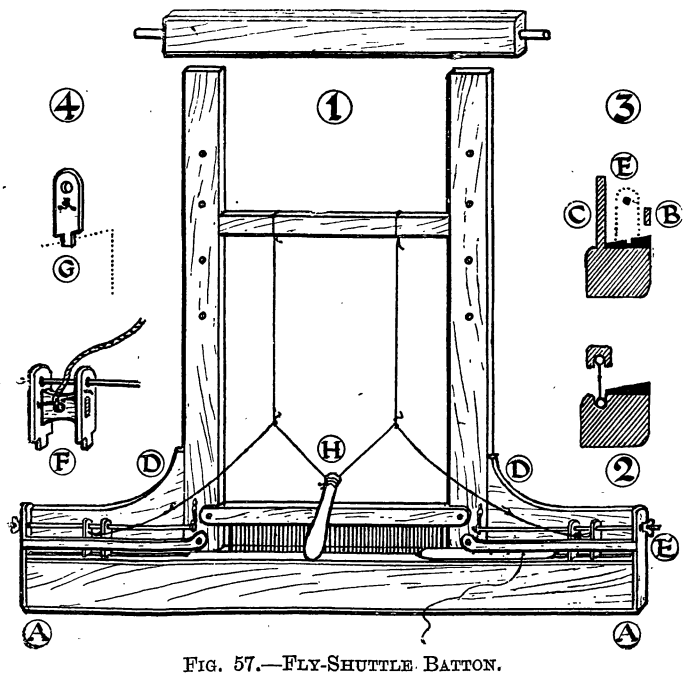

FIG. 57.—FLY-SHUTTLE BATTON.

the same manner. The two drivers are connected by a thin loose cord, having at its centre a handle. The loose cord is suspended from the bar above it merely in order to keep it off the level of the web. To drive the shuttle across the race, the weaver grasps the stick, after placing the shuttle in the box near the driver, and with a sudden jerk, to the side he wishes to send the shuttle, pulls the driver along the bar with just sufficient force to drive the shuttle into the opposite box. By a slight turn of the wrist—which is difficult to acquire and impossible to imitate by a machine—the opposite driver is brought forward to meet the shuttle as it enters the box. If this be properly done, there will not be the least rebound, and the weft will be laid evenly and straight. If, on the contrary, the shuttle be allowed to rebound, the shoot of weft will be loose, and when beaten down by the reed will show kinks and loops. Moreover the edges of the web will be uneven.

Previously to this invention all attempts to pass the weft through the shed, in machine-looms, failed to achieve anything like the speed of the hand-thrown shuttle, consequently they could not compete with the hand-loom. Even when the fly-shuttle method was adopted the difficulty of catching the shuttle baffled the skill of inventors for many years.

The attempts of inventors to produce an automatic broad-weaving machine resulted in the construction of many weird, though ingenious, contrivances bearing more or less likeness to the hand-loom in general use. Many of these were patented by their inventors, but failed to prove practically useful. It was not till 1786, when Dr. Edmund Cartwright devoted himself and his fortune to mechanical invention,

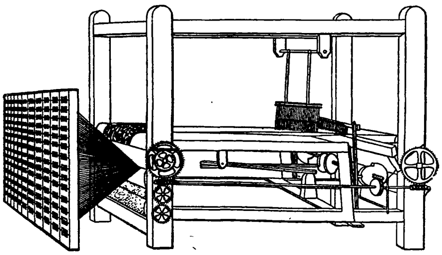

FIG. 58.—DR. CARTWRIGHT'S MACHINE-LOOM.

that a practical broad-weaving power-loom was evolved. Dr. Cartwright established a weaving and spinning factory at Doncaster, but after spending £30,000 and nine years in experiments he was obliged to give it up. He had, however, succeeded in devising a power-loom for plain weaving which it was believed could compete with the hand-loom. Several of his looms were bought by a Manchester firm and set up in a factory. They are said to have

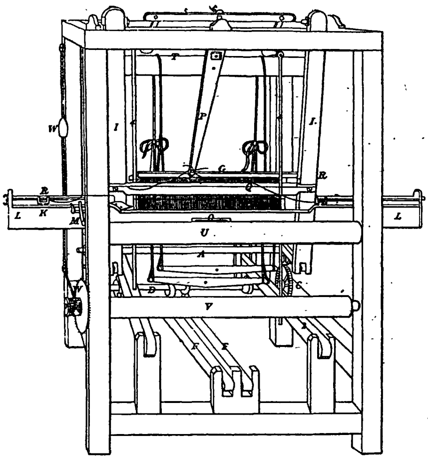

FIG. 59.—HORROCKS'S MACHINE-LOOM.

performed their work well, but the factory was, shortly after its starting, burned down by an infuriated mob of hand-loom weavers.

Fig. 58 is a photograph from one of Dr. Cartwright's designs for a power-loom. A careful examination of it, and its specifications, shows that the doctor had many ideas which were long afterwards adopted by improvers of power-loom machinery.

Fig. 59 is a drawing of a machine-loom constructed by a Mr. Horrocks a little later than Dr. Cartwright's time. It is said to have become largely used. It more closely resembles the fly-shuttle hand-loom than any of the other inventions. I should think it was only capable of weaving very faulty cloth.

By the end of the eighteenth century, it is said, there were 20,000 power-looms at work in Great Britain against 250,000 hand-looms. The power-looms, like the hand-looms, were constructed mostly of wood, and must have been clumsy and uncertain in their performances. Owing, too, to the greater strain of power weaving they must have quickly worn out.

It was a long time before a convenient form for the power-loom was generally adopted. Curiously enough, the form at length settled on was designed for a hand-loom in 1771.

The inventor of this loom (Fig. 60) was a Mr. Almond, who exhibited and worked it before the Society of Arts, and received a prize of £50 for his encouragement. Its chief feature is the inverted batton. It has also extra rollers, by

Hosted by Google

means of which the length of the loom is greatly diminished.

A power-loom erected for Mr. Monteith, a Glasgow manufacturer, about the beginning of the nineteenth century by a loom builder named Austin is extremely like Almond's hand-loom.

Mr. Austin presented a model of this loom to the Society of Arts, of which Fig. 61 is a representation.

Having settled on a general form suitable for the power-loom, inventors next directed their attention to strengthening it and perfecting as far as they could, its various parts. Take-up motions, contrivances for detecting broken threads, quickly stopping the loom, throwing the shuttle, etc., occupied their attention, and the loom became more and more accurate in its different performances as time went on.

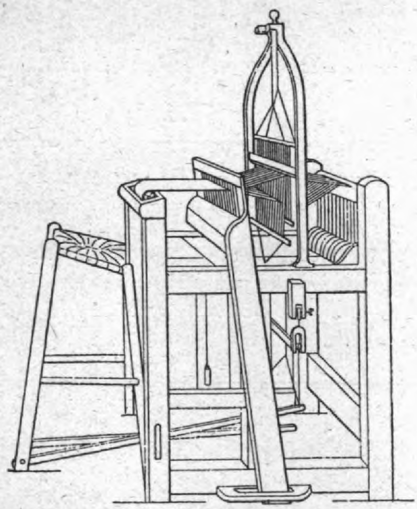

FIG. 60.—ALMOND'S LOOM.

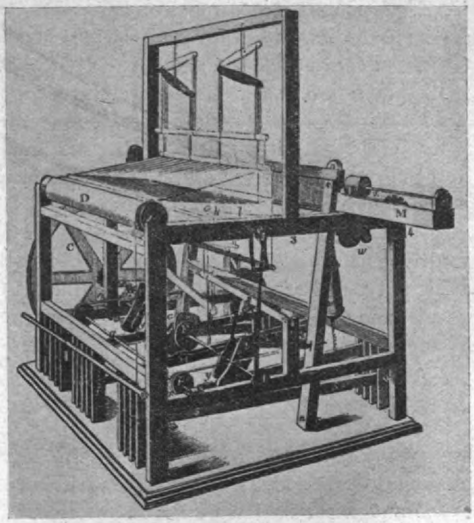

FIG. 61.—AUSTIN'S MACHINE-LOOM.

Iron took the place of wood all through the machine, and the loom, actuated by steam-power, has by now become, except in the matter of working the shuttle, a very perfect automatic machine.

Fig. 62 is a modern steam machine-loom for weaving silk. You will notice at once how the levers for driving the shuttle, and the shuttle-boxes, have increased in size and strength. It was found that, in order to catch the shuttle and prevent it rebounding, its entry into the opposite box had to be resisted. This rendered it necessary that the shuttle itself should be enormously increased in weight, and that great force should be used in driving it. Half the power expended in actuating the machine-loom is required thus to drive the shuttle into the opposite opposing box.

The addition and adaptation of the Jacquard machine to the power-loom was not attempted till late in the nineteenth century, but when that was done the loom had arrived at the point of development at which we find it to-day.

A few months ago my attention was called to an illustration in the *Manchester Guardian* which represented a new weaving invention, and, on reading the description of it, I found that the inventor—Mr. Whalley, of Clitheroe—claimed to have solved the problem of the shuttle, which I have pointed out has been the chief obstacle in the way of weaving by power.

Fig. 63 is a photograph of the new loom which appears to me to be likely to revolutionise

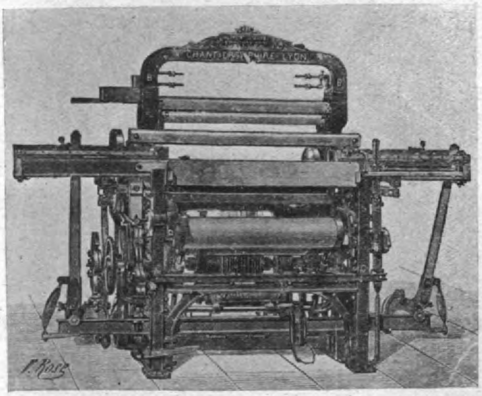

FIG. 62.—MODERN MACHINE-LOOM FOR SILK WEAVING.

Hosted by Google

the construction of machines for weaving by power.

Although, at first sight, this loom seems to be altogether different from previous inventions,

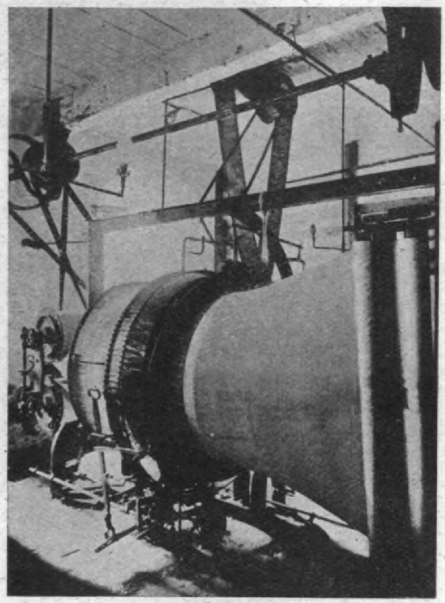

FIG. 63.—WHALLEY'S CIRCULAR MACHINE-LOOM.

an examination of it proves that in most essential points the tradition of weaving, which I have attempted to explain, still governs it. Three great advantages are claimed for it—(1) it is practically noiseless; (2) the weft has no jerk or strain upon it; (3) very little power is required to drive it. In addition to this, webs of between eleven and twelve feet wide are woven on it.

There is not time for me to give an adequate description of this important invention, but I must notice its salient points, and show (1) how it differs from the ordinary power-loom, and (2) how the traditional principles of weaving are still carried on in it.

First, as to points of difference: All the operations of the loom are worked out by its simply turning on its own accurately centred axis.

By an uninterrupted circular movement in one direction the warp is drawn off the warp-beam, the shed is opened and the weft inserted, the weft itself is gently pressed close instead of being beaten together, and the woven web is delivered and rolled on to the cloth beam without any strain or jerk whatever.

There is no shuttle. A case for the flexible cop of wound weft takes its place. The cop itself is of enormous length and holds a hitherto unheard-of quantity of yarn.

While the whole loom and its fittings revolve, the cop case remains stationary, balanced in the shed, and allows the weft to be drawn off it continuously in one direction, as, at each revolution, the successive sheds are opened. This forms, of course, a spiral thread in the woven cloth, the cloth itself being produced in the form of an enormous tube. As the cloth passes on to the cloth beam an automatic knife cuts it at a place where specially woven doup selvages are made.

So far all is new. The rest of the mechanism is an ingenious rearrangement of the traditional parts of a loom. The description of these essential parts requires a diagram of a section of the loom, which we have in Fig. 64.

In the centre of the section is the steel axis, which runs the whole length of the loom.

The perforated comber board, instead of being straight and horizontal, as in the ordinary loom, is circular, and is duplicated, the holes being most accurately pierced.

The holes in these circular comber boards are very close together, and there are as many holes as there are threads of warp.

In each of these holes there is a long steel needle, with its eye in the centre, the needle itself being rather more than twice as long as the space between the two comber boards.

These needles fit loosely into the holes of the

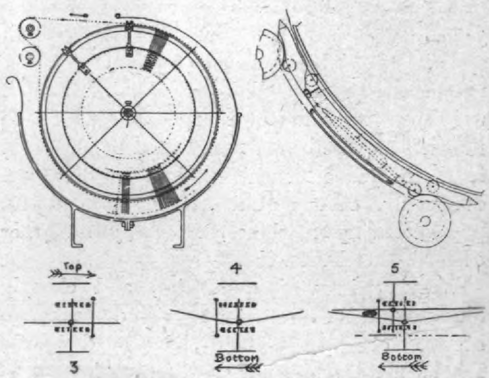

FIG. 64.—SECTION OF WHALLEY'S LOOM.

comber boards, so that when they reach, as the loom revolves, a position above the horizontal centre of the machine they rest against the central core of the loom.

But when in turn the needles come below the horizontal centre they project through the holes

of the outer perforated circle as shown in the drawing.

A thread from the warp-beam is drawn through the eye of each needle, and, when passed through the circular reed and fastened to the cloth beam, will, of course, follow the movement of the needle as it falls against the core at the top or projects through the holes of the outer comber-ring. This is shown at Nos. 3 and 4, which are longitudinal sections.

An endless band of cards, similar to those used for the Jacquard machine, fits to the outer rim and governs the design. Where these cards have holes in them the needles fall through and draw down the warp thread entered in them, but where the card is plain the needle retains its position. This is shown at No. 5, where an open shed is represented.

No. 2 shows the cop of weft in its case in position for working, where it is retained by two smooth bowls of bosses fixed in their places on the stand or under-framework of the loom. The opened shed surrounds the cop case, passes along it, and when it leaves it, it of course encloses the weft.

By an arrangement at the top of the loom the reed is slightly pushed forward, so that it gently presses the weft into its place as it passes a certain point. Very little pressure is sufficient, as only a few inches are affected at a time.

Time forbids me to attempt a description of other details of the circular loom, some of which, no doubt, will be altered and improved. But sufficient has, I hope, been described for the general idea of the machine to be understood, and its great achievement, the continuous wefting contrivance, to be appreciated. Although the hopes of the inventor of this circular loom may not at once be realised, I shall be surprised if the principle on which it works does not eventually become universally adopted for power-weaving machines, especially for plain or small-patterned webs.

Weaving in vast quantities, and cheaply imitating, in inferior materials, rich damasks and brocades of important and elaborate design is, I hold, neither wise nor desirable. The use of machine-looms for this kind of work is, therefore, to be deprecated. The tender manipulation required for weaving the varying textures of the finest webs made in the eighteenth century, and in China and the East generally, is only possible on a loom as sensitive as the perfected draw-loom, and by a craftsman who, understanding every detail of the mechanism, is capable of controlling it. If such perfect work be required, it must be done on a hand-loom.

This loom, however, need not be as cumbrous as the old draw-loom, nor as noisy and intricate as one fitted with the Jacquard machine. If I may don the mantle of the prophet, I should say three things will be retained, and will continue the tradition of the past in the hand-loom of the future. With an indication of these I must conclude my lectures.

1. The skilful manipulation of the hand-shuttle for work not too wide for it, and of the fly-shuttle for broader webs, cannot be improved upon. It will, therefore, be retained.

2. The perforated comber board (Fig. 45), which, as I showed last week, was an ancient Chinese invention, must be retained. Probably, however, some arrangement of metal needles, such as those of the circular loom just described, will be substituted for the string leashes with their mails and lingoes. But all the upper complications of strings and cords will be dispensed with.

3. The principle of working out the design by punching holes in a band of cards will be retained, although the Jacquard machine itself will, I imagine, be superseded by an electro-magnet placed above the comber board. This magnet will attract the metal needles and raise the warp, some arrangement being made so that only those needles wanted for making the required shed will be raised.

Everything else may go, and new contrivances be introduced, but it is on some such hand-loom as this that I can imagine the master-weaver of the future being able, not only to produce webs as exquisite as those of the best weavers of the past, but to carry the art forward to a higher degree of perfection than it has ever yet attained.

HEALTH AND VENTILATION.*

Everyone thinks that he suffers in an ill-ventilated room owing to some change in the chemical quality of the air, be it want of oxygen, or excess of carbon dioxide, the addition of some exhaled organic poison, or the destruction of some subtle property by passage of the air over steam-coils, or other heating or conducting apparatus. We hear of "devitalised" or "dead" air, and of "tinned" or "potted" air of the battleship. The good effects of open-air treatment, sea and

* Extracts from the Presidential Address to the Physiological Section of the British Association, by Leonard Hill, M.B., F.R.S.

Hosted by Google

mountain air, are no less generally ascribed to the chemical purity of the air. In reality the health-giving properties are those of temperature, light, movement, and relative moisture of the surrounding atmosphere, and leaving on one side those gross chemical impurities which arise in mines and in some manufacturing processes, and the question of bacterial infection, the alterations in chemical composition of the air in buildings where people crowd together and suffer from the effects of ill-ventilation have nothing to do with the causation of these effects.

Satisfied with the maintenance of a specious standard of chemical purity, the public has acquiesced in the elevation of sky-scrapers and the sinking of cavernous places of business. Many have thus become cave-dwellers, confined for most of their waking and sleeping hours in windless places, artificially lit, monotonously warmed. The sun is cut off by the shadow of tall buildings and by smoke—the sun, the energiser of the world, the giver of all things which bring joy to the heart of man, the fitting object of worship of our forefathers.

The ventilating and heating engineer hitherto has followed a great illusion in thinking that the main objects to be attained in our dwellings and places of business are chemical purity of the air and a uniform draughtless summer temperature.

Life is the reaction of the living substance to the ceaseless play of the environment. Biotic energy arises from the transformation of those other forms of energy—heat, light, sound, etc.—which beat upon the transformer—the living substance. Thus, when all the avenues of sense are closed, the central nervous system is no longer aroused and consciousness lapses. Laura Bridgeman, paralysed in almost all her avenues of sense, fell asleep whenever her remaining eye was closed. The patient who lost one labyrinth by disease and, to escape unendurable vertigo, had the other removed by operation, was quite unable to guide his movements or realise his position in the dark. Rising from bed one night, he collapsed on the floor and remained there helpless till succour arrived.

A sense organ is not stimulated unless there is a change of rate in the transference of energy; and this to be effectual must occur in most cases with considerable quickness. If a weak agent is to stimulate, its application must be abrupt. Thus the slow changes of barometric pressure on the body-surface originate no skin sensations, though such changes of pressure, if applied suddenly, are much above the threshold value for touch. A touch excited by constant mechanical pressure of slight intensity fades quickly below the threshold of sensation. Thus the almost unbearable discomfort which a child feels on putting on for the first time a "natural" wool vest fades away, and is no longer noticed with continual wear. Thomas à Becket soon must have become oblivious to his hair-shirt, and even to its harbingers. It is not the wind which God tempers to the shorn lamb, but the skin of the lamb to the wind. The inflow of sensations keeps us active and alive, and all the organs working in their appointed functions. The cutaneous sensations are of the highest importance. The salt and sand of wind-driven sea air particularly act on the skin and through it braces the whole body. The changing play of wind, of light, cold, and warmth, stimulate the activity and health of mind and body. Monotony of sedentary occupation and of an overwarm still atmosphere endured for long working hours destroys vigour and happiness, and brings about the atrophy of disuse. We hear a great deal of the degeneration of the race brought about by city life, but observation shows us that a drayman, navvy, or policeman can live in London, or other big city, strong and vigorous, and no less so than in the country. The brain-worker, too, can keep himself perfectly fit if his hours of sedentary employment are not too long and he balances these by open-air exercise. The horses stabled, worked, and fed in London are as fine as any in the world; they do not live in windless rooms heated by radiators.

The hardy men of the North were evolved to stand the vagaries of climate—cold and warmth—a starved or full belly have been their changing lot. The full belly and the warm sun have expanded them in lazy comfort; the cold and the starvation have braced them to action. Modern civilisation has withdrawn many of us from the struggle with the rigours of Nature; we seek for and mostly obtain the comfort of a full belly and expand all the time in the warm atmosphere afforded us by clothes, wind-protected dwellings, and artificial heat—particularly so in the winter, when the health of the business man deteriorates. Cold is not comfortable, neither is hunger, therefore we are led to ascribe many of our ills to exposure to cold, and seek to make ourselves strong by what is termed good living. I maintain that the bracing effect of cold is of supreme importance to health and happiness, that we become soft and flabby, and less resistant to the attacks of infecting bacteria in the winter, not because of the cold but because of our excessive precautions to preserve ourselves from cold; that the prime cause of "cold" or "chill" is not really exposure to cold but to the over-heated and confined air of rooms, factories, and meeting-places. Seven hundred and eleven survivors were saved from the "Titanic" after hours of exposure to cold. Many were insufficiently clad and others wet to the skin. Only one died after reaching the "Carpathia," and he three hours after being picked up. Those who died perished from actual cooling of the body. Exposure to cold did not cause in the survivors the diseases commonly attributed to cold.

The conditions of great cities tend to confine the worker in the office all day, and to the heated atmosphere of club, cinema show, or music-hall in the evening. The height of houses prevents the town dweller from being blown upon by the wind, and, missing the exhilarating stimulus of the

Hosted by Google

cool, moving air, he repels the dull uniformity of existence by tobacco and by alcohol, or by indulgence in food, *e.g.*, sweets, which are everywhere to his hand, and by the nervous excitement of business and amusement. He works, he eats, and is amused in warm, windless atmospheres, and suffers from a feeble circulation, a shallow respiration, a disordered digestion, and a slow rate of metabolism.

Experimental evidence is strongly in favour of my argument that the chemical purity of the air is of no importance. Analyses show that the oxygen in the worst-ventilated school-room, chapel, or theatre is never lessened by more than 1 per cent. of an atmosphere; the ventilation through chink and cranny, chimney, door, and window, and the porous brick wall, suffices to prevent a greater diminution. So long as there is present a partial pressure of oxygen sufficient to change the hæmoglobin of the venous blood into oxyhæmoglobin, there can arise no lack of oxygen.

At sea-level the pressure of oxygen in the pulmonary alveolar air is about 100 mm. Hg. Exposed to only half this pressure the hæmoglobin is more than 80 per cent. saturated with oxygen.

In noted health-resorts of the Swiss mountains the barometer stands at such a height that the concentration of oxygen is far less than in the more ventilated room. On the high plateau of the Andes there are great cities: Potosi with a hundred thousand inhabitants is at 4,165 metres, and the partial pressure of oxygen there is about 13 per cent. of an atmosphere in place of 71 per cent. at sea-level; railways and mines have been worked up to altitudes of 14,000 to 15,000 feet. At Potosi girls dance half the night, and toreadors display their skill in the ring. On the slopes of the Himalayas shepherds take their flocks to altitudes of 18,000 feet. No disturbance is felt by the inhabitants or those who reach these great altitudes slowly and by easy stages. The only disability to a normal man is diminished power for severe exertion, but a greater risk arises from want of oxygen to cases of heart disease, pneumonia, and in chloroform anæsthesia at these high altitudes. The newcomer who is carried by the railway in a few hours to the top of Pike's Peak or the Andes may suffer severely from mountain sickness, especially on exertion, and the cause of this is want of oxygen. Acclimatisation is brought about in a few days' time. The pulmonary ventilation increases, the bronchial tubes dilate, the circulation becomes more rapid. The increased pulmonary ventilation lowers the partial pressure of carbon dioxide in the blood and pulmonary air, and this contributes to the maintenance of an adequate partial pressure of oxygen. Haldane and Douglas say that the percentage of red corpuscles and total quantity of the hæmoglobin increase, and maintain that the oxygen is actively secreted by the lung into the blood, but the method by which their determinations have been made has not met with unqualified acceptance. If waste products, which arise from oxygen want, alter the combining power of hæmoglobin, this alteration may not persist in shed blood; for these products may disappear when the blood is exposed to air. Owing to the combining power of hæmoglobin, the respiratory exchange and metabolism of an animal within wide limits is independent of the partial pressure of oxygen. On the other hand, the process of combustion is dependent, not on the pressure, but on the percentage of oxygen. Thus the aeroplanist may become seized with altitude sickness from oxygen want, while his gas engine continues to carry him to loftier heights.

The percentage of CO_2 in the worst ventilated room does not rise above 0·5 per cent., or at the outside 1 per cent. It is impossible that any excess of CO_2 should enter into our bodies when we breathe such air, for whatever the percentage of CO_2 in the atmosphere may be, that in the pulmonary air is kept constant at about ·5 to ·6 per cent. of an atmosphere—by the action of the respiratory centre. It is the concentration of CO_2 which rules the respiratory centre, and to such purpose as to keep the concentration both in the lungs and in the blood uniform; the only result from breathing air containing 0·5 to 1 per cent. of CO_2 is an inappreciable increase in the ventilation of the lungs. The very same thing happens when we take gentle exercise and produce more CO_2 in our bodies.

At each breath we rebreathe into our lungs the air in the nose and large air-tubes (the dead-space air), and about one-third of the air which is breathed in by a man at rest in dead-space air. Thus, no man breathes in pure outside air into his lungs. When a child goes to sleep with its head partly buried under the bed-clothes, and in a cradle confined by curtains, he rebreathes the expired air to a still greater extent, and so with all animals that snuggle together for warmth's sake. Not only the new-born babe sleeping against its mother's breast, but pigs in a sty, young rabbits, rats, and mice clustered together in their nests, young chicks under the brooding hen, all alike breathe a far higher percentage than that allowed by the Factory Acts.

To rebreathe one's own breath is a natural and inevitable performance, and to breathe some of the air exhaled by another is the common lot of men who, like animals, have to crowd together and husband their heat in fighting the inclemency of the weather.

The sanitarian says it is necessary to keep the CO_2 below 0·01 per cent., so that the organic poisons may not collect to a harmful extent. The evil smell of crowded rooms is accepted as unequivocal evidence of the existence of such. He pays much attention to this and little or none to the heat and moisture of the air. The smell arises from the secretions of the skin, soiled clothes, etc. The smell is only sensed by and excites disgust in one who comes to it from the outside air. He who is inside and helps to make the "fugg" is both wholly unaware of and unaffected by it. Flügge points out, with justice, that while we naturally

Hosted by Google

avoid any smell that excites disgust and puts us off our appetite, yet the offensive quality of the smell does not prove its poisonous nature. For the smell of the trade or food of one man may be horrible and loathsome to another not used to such.

Ventilation cannot get rid of the source of a smell, while it may easily distribute the evil smell through a house. As Pettenkofer says, if there is a dung-heap in a room, it must be removed. It is no good trying to blow away the smell.

To study the relative effect of the temperature and chemical purity of the atmosphere, I constructed a small experimental chamber of wood fitted with large glass observation windows and rendered air-tight.

On one side of the chamber were fixed two small electric heaters, and a tin containing water was placed on these in order to saturate the air with water vapour. On another side of the chamber was placed a large radiator through which cold water could be circulated when required, so as to cool the chamber. In the roof were fixed three electric fans, one big and two small, by means of which the air of the chamber could be stirred. The chamber held approximately 3 cubic metres of air. In one class of experiments we shut within the chamber seven or eight students for about half an hour, and observed the effect of the confined atmosphere upon them. We kept them until the CO_2 reached 3 to 4 per cent., and the oxygen had fallen to 17 to 16 per cent. The wet-bulb temperature rose meanwhile to about 80° to 85° F., and the dry bulb a degree or two higher. The students went in chatting and laughing, but by-and-by, as the temperature rose, they ceased to talk and their faces became flushed and moist. To relieve the monotony of the experiment we have watched them trying to light a cigarette, and, puzzled by their matches going out, borrowing others, only in vain. They had not sensed the diminution of oxygen, which fell below 17 per cent. Their breathing was deepened by the high percentage of CO_2, but no headache occurred in any of them from the short exposure. Their discomfort was relieved to an astonishing extent by putting on the electric fans placed in the roof. Whilst the air was kept stirred the students were not affected by the oppressive atmosphere. They begged for the fans to be put on when they were cut off. The same old stale air containing 3 to 4 per cent. CO_2 and 16 to 17 per cent. O_2 was whirled, but the movement of the air gave relief, because the air was 80° to 85° F. (wet bulb), while the air enmeshed in their clothes in contact with their skin was 98° to 99° F. wet bulb. If we outside breathed through a tube the air in the chamber we felt none of the discomfort which was being experienced by those shut up inside. Similarly, if one of those in the chamber breathed through a tube the pure air outside he was not relieved.

I have made observations on men dressed in the Fleuss rescue apparatus for use in mines, and exposed in a chamber to 120° F. dry bulb and 95° F. wet bulb. The skin temperature rises to the rectal temperature, and the pulse is greatly accelerated—*e.g.*, to 150—and there arises danger of heat stroke. The conditions are greatly relieved by interposing on the inspiratory tube of the apparatus a cooler filled with carbonic-acid snow. The cool inspired air lowers the frequency of the heart, and makes it possible for the men to do some work at 95° F. wet bulb, and to endure this temperature for two hours.

I conclude, then, that all the efforts of the heating and ventilating engineer should be directed towards cooling the air in crowded places and cooling the bodies of the people by setting the air in motion by means of fans. In a crowded room the air confined between the bodies and clothes of the people is almost warmed up to body temperature and saturated with moisture, so that cooling of the body by radiation, convection and evaporation becomes reduced to a minimum. The strain on the heat-regulating mechanism tells on the heart. The pulse is accelerated, the blood is sent in increased volume to the skin, and circulates there in far greater volume, while less goes through the viscera and brain. As the surface temperature rises, the cutaneous vessels dilate, the veins become filled, the arteries may become small in volume, and the blood-pressure low, the heart is fatigued by the extra work thrown upon it. The influence of the heat stagnation is shown by the great acceleration of the pulse when work is done and the slower rate at which the pulse returns to its former rate on resting.

The increased percentage of carbonic acid and diminution of oxygen which has been found to exist in badly ventilated churches, schools, theatres, barracks, is such that it can have no effect upon the incidence of respiratory disease and higher death-rate, which statistical evidence has shown to exist among persons living in crowded and unventilated rooms. The conditions of temperature, moisture, and windless atmosphere in such places primarily diminishes the heat loss, and secondarily the heat production, *i.e.*, the activity of the occupants, together with total volume of air breathed, oxygen taken in and food eaten. The whole metabolism of the body is thus run at a lower plane, and the nervous system and tone of the body is unstimulated by the monotonous, warm and motionless air. If hard work has to be done it is done under conditions of strain. The number of pathogenic organisms is increased in such places, and these two conditions run together—diminished immunity and increased mass influence of infecting bacteria.

THE CORK INDUSTRY IN ALGERIA.

The natural forests of cork trees in Algeria are amongst the chief sources of wealth in that colony. This tree, which is a species of oak, is indigenous to nearly the whole of the northern coast of Africa. In Algeria the principal centres of production are situated in the Department of Constantine, where the forests of cork trees in the district of

Hosted by Google

Philippeville cover an area of upwards of 200,000 hectares (nearly half a million of English acres).

Cork is also grown in the western part of the Department of Algiers; it is more rare in the Department of Oran, where it is to be found near Tlemcen and a few other localities.

The production of cork in this colony has increased very considerably during the last quarter of a century. In 1890 the total quantity of cork exported to France and other countries, which amounted to 94,387 quintals (185,801 cwts.) only, amounted in 1910 to 310,376 quintals (610,976 cwts.).

The Algerian cork, which is of excellent quality, is exported principally to Russia, Germany, Austria, Belgium, Holland, Spain, and the United States.

The cork industry is well organised in Algeria, and cork cutting, packing and sorting and all other branches of the trade are carried on, on a large scale, by many firms established at Algiers, Bougie, Philippeville, and Djidjelli, who either purchase the raw cork direct from the forests controlled by the Government or from private owners.

A large trade in corks for bottles is carried on in most of the principal towns, such as Algiers, Oran, Bougie, Djidjelli, Collo, Philippeville, Bona, Calle and Constantine.

The virgin cork, which at one time was considered valueless, now finds a good market in England and Germany.

The cork is principally shipped from the ports of Algiers, Bougie, Oran, Philippeville and Bona.

The export of cork from these ports shows an increasing tendency since 1902, as will be seen by the following statement:—

	To France.	To Other Countries.	Total Exports.	
	Quintals.	Quintals.	Quintals.	English tons.
1902	30,191	40,589	70,780	6,956
1905	79,866	161,645	241,511	23,771
1908	93,506	182,592	276,098	27,175
1910	80,986	229,390	310,376	30,549

THE COCONUT INDUSTRY OF PANAMA.

Panama has for generations been famous for coconuts, and one of the best known poets of the tropics has called that region "the land of the coconut tree." These nuts form one of the staple exports of Panama, over £30,000 worth having been sent in 1910 to the United States. The coconut-palm is said to have as many uses as there are days in the year; and it supplies man with food, drink, medicine, clothing, light, and household utensils. Whether the tree came originally from the Eastern Archipelag native of America—and this latter h according to the International Union of Republics, seems the more tenable—it ha all over the tropics, and grows wild or is c in every country of the Pan-American Usually seen along the coast, it nevertheless well at an elevation of 4,500 feet above the of the sea. The life of the bearing tree ma the century mark, but the best productive of the coconut-palm is from eight to fort It begins to yield, if in favourable condi the fifth year, and yields a profitable harv cultivator. The coconut is really, at t time, a commercial article, and is fin more and more into the markets Twenty-eight per cent. of all the coc in the world are grown in the Ame however, they are scattered over a m area for each palm than is the case thereby making the work of collecting more difficult and expensive. Th natural palm regions have never worked, but the approaching comp Panama Canal will rapidly bring within the radius of profit. Both coas have already benefited by the increase for transport of the last few years, and tions are receiving fresh attention, whil areas, on both mainland and islands their long-standing popularity.

PRODUCTION OF CAPERS SOUTH OF FRANC

Capers, the flower-buds of the ca still a product of some importance of France, notwithstanding that th grown in Corsica, Algeria, Tunis, Spai in the Crimea. The capers of Prov seems to be the natural home of the pl considered to be superior in quality to those elsewhere, but the falling-off of the produc here must be attributed to foreign competiti The growing of capers in France is almost exclsively restricted to the Departments of the Var an Bouches-du-Rhône between Marseilles and Toulon.

It is, however, only on the hills of Roquevaire, about twelve miles north-east, and Cuges, sixteen miles east of Marseilles, that a regular cultivation of this plant may be said to exist. At Cuges, where formerly 30 hectares (about 75 acres) were cultivated, and produced annually upwards of 180,000 kilogs. (396,900 lbs. = 177 tons), the production at the present time of capers does not exceed 70,000 to 80,000 kilogs. (70 to 80 tons). The total production of Provence is now estimated at 150,000 kilogs. (330,750 lbs. = 147¾ tons) yearly.

The gathering of the capers usually commences towards the end of May, as soon as the buds are the size of a small pea, and the picking continues all the month of June. The bushes are picked

Hosted by Google

once a week at first, and oftener as the season ses, so as not to allow the buds to become too This is done chiefly by women, who, on an ge, can collect 12 kilogs. to 15 kilogs. (26½ lbs. lbs.), whilst an exceptionally good worker etimes picks even 20 kilogs. (44 lbs). The king is paid for at the rate of 25 cents. to cents. per kilog. (1¼d. to 1½d. per lb.) for this rk.

e bushes yield from ½ kilog. to 2½ kilogs. (1 lb. lbs.) of capers every season.

r being stripped of any loose leaves, and the cotton round them removed, the buds ed by being passed through sieves with zed meshes. They are then spread (not on cloths to dry in shady and well- rooms. When dry, and ready for pre- hey are placed in jars or other vessels g strong wine vinegar, which sometimes d with tarragon or other herbs.

re classified according to size, the best, *i-pareilles*, those passed through a meshes of 6 millimetres (·2362 inch); w the *surfines*, through 8-millimetre 19 inch); the *capucines*, a 9-millimetre 43 inch); and the *capotes*, a 10-milli- esh (·3937 inch). The coarser varieties vn as *fines* and *demi-fines*. The capers s district are chiefly exported to London, , and Hamburg.

T OF EGGS FROM RUSSIA.

rade in Russia appears to be in a very condition at the present time, judging atistics published by the Custom House of that country. The following figures ncrease of 22·84 per cent. in number, and e value of the eggs exported in 1911, as with those in 1910:—

	Number.	Roubles.*	£ Sterling.
1911 . . .	3,683,000,000	80,747,000	8,523,294
1910 . . .	2,998,000,000	63,700,000	6,723,888
Increase . .	685,000,000	17,047,000	1,799,406

The number of eggs exported last year from Russia to the principal commercial nations of Europe, was as follows:—

United Kingdom . .	1,308,000,000
Germany	1,118,000,000
Austria-Hungary . .	793,000,000
Denmark	78,000,000
Other Countries . .	386,000,000
	3,683,000,000

* The rouble = 100 kopecks = 2s. 1⅓d. The kopeck = about one farthing.

The prices, on the spot, last year, have ranged higher than has been the case during the four previous years, and averaged 21 roubles 92 kopecks (£2 6s. 3d.) per 1,000 in 1911, as compared with 21 roubles 24 kopecks (£2 4s. 10d.) in 1910; 21·87 roubles (£2 6s. 2d.) in 1909; 21·19 roubles (£2 4s. 9d.) in 1908; and 21·43 roubles (£2 5s. 3d.) in 1907. The highest prices reached were at Kazan, when they averaged 24 to 25 roubles (£2 10s. 8d. to £2 12s. 9½d.) per 1,000.

OBITUARY.

JOHN LEIGHTON, F.S.A.—By the death of Mr. John Leighton, which took place at Harrow on the 15th inst., on his ninetieth birthday, the Society loses one of its oldest members, as he became a life member in 1851. Mr. Leighton's work takes us back to the Exhibition of 1851, as some of the exhibits of bookbinding shown there were from his designs. In some of the obituary notices which appeared in the daily papers, it was stated that he was a member of the Royal Commissions for the Exhibitions of 1851 and 1862; but this is not correct.

He was a prolific and excellent designer and book illustrator, and produced also a number of books, some of which were issued under the pseudonym of "Luke Limmer." The volumes of the *Journal*, from the seventh down to the fifty-first, are full of communications from him on the most varied subjects. In 1859 he read an admirable paper on Bookbinding, which contains much valuable information, and may still be referred to with advantage. A second paper read by him in 1888 on a method of conducting elections through the post contained a proposal which was sensible enough, but of no special originality. He was a very frequent attendant at the Society's meetings, and constantly took part in the discussions during a period of nearly fifty years. Most of his remarks dealt with artistic matters, and were of value. But he was a man of singularly versatile interests, and he was always ready to speak on matters of which he had no special knowledge, though his remarks were often shrewd and interesting. The last occasion on which he took part in the discussion was in 1902, when he made a few remarks on a paper read by Dr. Gustave Goegg on the Simplon tunnel and railway. His great age and failing health prevented his taking part in the Society's meetings, or producing any artistic work, of late years. But his work extended throughout the whole of the last half of the nineteenth century, and during that long period he contributed his share to the progress of design, and he was certainly one of the pioneers in the advance of industrial art.

GENERAL NOTES.

The Cultivation of the Castor Bean in Jamaica.—The remunerative prices which castor oil is bringing in foreign markets have awakened renewed interest in the castor plant. The industry apparently is one that does not require much skill in planting, and, once established, the seeds propagate themselves, fertilising the soil not being necessary. The plant has been cultivated by the Jamaican peasantry for years, and a considerable acreage is now under cultivation. In the East Indies, where the castor bean is extensively cultivated, it yields as much as five tons of seeds to the acre. In Jamaica there are several species, and recent experiments show that the nut grown there gives a larger yield of oil than the East Indian product. Experience seems to indicate that the castor plant is practically immune from insect pests. The oil has become very popular of late as a lubricant. No doubt machinery for crushing the seeds will shortly be required.

The Tanning Industry in Spain.—The tanning of leather is of considerable importance in Spain. There are no official statistics published regarding this industry, but a reliable estimate by persons well informed on the subject places the total number of tanneries in the country at about fifteen hundred, employing approximately 22,500 work-people. Although these tanneries are distributed over the entire country, the Catalonia district is the principal centre of the industry, there being in the city of Barcelona alone about one hundred factories, turning out a great variety of products as sole leather, tanned cowhides and calfskins, morocco leather, dressed sheep and other skins, etc. The greater part of the leather produced finds its way to the numerous shoe factories in Catalonia and the Balearic Islands. Besides supplying practically the entire home demand, the Spanish tanneries also export their manufactures to foreign countries, Barcelona being the chief port of export, followed by Valencia and Palma. Heretofore the leather was all tanned by the old method—that is, leaving the raw hides in the extract for a few weeks; but the factories are now beginning to adopt the modern methods, by which the hides can be tanned in a much shorter period.

Oil for Use in making Umbrellas in Japan.—The vegetable oil used in making paper umbrellas in Japan is pressed out of the seeds of *Perilla ocimoides*, an annual plant which resembles *Perilla perkinensis*. This oil is made in the Tochigi, Saitama, Chiba, Miyagi and Ibaraki prefectures. These prefectures are famous for the production of the seeds and oil. Sandy ground is favoured for the cultivation of the plant, and the oil is extracted from the seeds by presses. The yield of seeds is estimated at twenty bushels per acre. The annual production throughout Japan amounts to 300,000 to 350,000 bushels, from which over a gallon of oil per bushel is extracted, according to Japanese statistical returns. The oil before being used is boiled and then cooled until it can be applied by hand to umbrellas with a piece of cloth or
No machinery or tools are used in applyin
oil. When the oiling is completed the umbr
are exposed in the sun for about five hours.
oil is also used in making paper lanterns, oil p
and artificial leather, and in preparing materials
making printing ink, paints, varnish, and lacquer.

Syrian Apricot Paste.—The apricot pas
industry has long been in vogue in Damascus a
all along the valley of the Barada River. T
methods employed are very simple. A hole,
or three feet deep, and of a circumference
portionate to the crop to be treated, is dug b

From this farm there has been an export to t
following places, viz., Basle, Milan, Palermo,
Havana, St. Antonio, Paris, and London. A big
turnover is done by the selling of ostrich feather goods, which are made up by the hands of the factory connected with the farm and sent to all parts of the world. The factory now employs over 300 hands, all the girls being paid by piece work and earning good wages. The commerce of the port of Nice is in a fair way to experience great development, as a new line of railway, opened recently, has placed Grenoble within easier reach of Nice than of Marseilles, while an Italian line under construction will prove equally beneficial in connecting Cuneo and Turin with Nice. An improvement in the Paris, Lyons, and Marseilles service, too, has, for the first time, brought the chief towns of the French Riviera in direct fast communication with Paris, as regards second and third-class passengers. This will prove a convenience to English travellers, as until the change the fast evening train from Paris did not go beyond Marseilles.

Journal of the Royal Society of Arts.

No. 3,123. VOL. LX.

FRIDAY, SEPTEMBER 27, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICE.

EXAMINATIONS.

The programme of the Society's examinations for the coming year is now ready, and copies have been sent to the examination centres throughout the United Kingdom. (These now number nearly 500.)

The programme contains the regulations, time-table, syllabuses for all subjects, the papers set in 1912, together with the examiners' reports on the work done, and a summary of the results for 1912.

Copies may be obtained on application to the Secretary, price 3*d.*, post free 4½*d.*

It is hoped, in the course of the next year or two, that the examinations will everywhere be conducted and supervised by the local education authorities only. As stated in the *Journal* of February 16th last, a start in this direction was made in London this year, and the London County Council Education Committee now undertakes the entire supervision of the examinations in the County of London, where nearly 10,000 candidates sat for examination in 1912.

Efforts are now being made to bring about a similar state of things in the large cities and towns where the examinations are held. In most of the smaller places this is already the case. The Council are of opinion that by placing the supervision of the examinations in the hands of independent local authorities the value of the Society's certificates will be greatly enhanced.

In 1912, in the commercial examinations, 28,057 candidates worked 34,002 papers. In addition to these, 296 candidates were examined in practice of music, 633 took the viva voce examination in modern languages, and there were 45 candidates for the special Army shorthand examination. Altogether, therefore, 29,031 candidates were examined by the Society this year.

THE ROYAL SOCIETY OF ARTS.*

By Sir Henry Trueman Wood, M.A.,
Secretary of the Society.

X.—The Presidency of the Prince Consort.
(1843–1861.)

In the last article which dealt with the internal organisation and constitution of the Society,† we left off at the point when a Council had just been appointed, and a Charter obtained for the Society. The task before the new Council was no light one, and it started on its work of reform with many difficulties in the way. It had to rescue the Society from the condition of torpor and ineptitude into which it had fallen, to arrange its finances, and indeed to provide funds for its work. It had to justify its existence, to rouse public interest, and to find fresh directions for its efforts to carry out the objects for which the Society was originally founded. To do this, it had first to organise itself, and to distribute the work between itself and the various committees into whose hands the details might safely be entrusted. At first the original six "Premium" Committees were maintained, the committee on "Miscellaneous Matters" being merged in the Council. But it is hardly worth while to enter into an account of the various changes which were made in the number and duties of the committees. Sometimes the number was increased; sometimes it was diminished; at one time there were as many as thirty. But eventually the sensible system was adopted of appointing committees from time to time as questions arose for their consideration.

Inasmuch as all the business of the Society at once passed under the control of the new governing body, there was nothing left to occupy the attention of the ordinary meetings, which had

* The previous articles of the series appeared in the *Journals* of June 9th and 16th, September 22nd and 29th, November 3rd, 1911, January 12th, 19th and 26th, April 5th, June 14th and 21st, and July 12th, 1912.

† *Journal*, April 5th, 1912, p. 527.

Hosted by Google

hitherto been taken up in the award of the premiums, and in the continual discussion of the Society's rules and orders. This naturally led to an increased importance in the scope and character of the papers, the reading of which rapidly became, at first, the most important, and very soon the only function of these meetings. By the time we have now reached, the system started by Aikin had grown and developed, until it became the recognised practice for every Wednesday evening during the session to be occupied, either by a paper, followed by a discussion, on some new invention or some novel industrial development, or else by a lecture (which was not discussed) on some branch of industry, some fresh application of science, or, less frequently, some application of artistic principles or methods.

Perhaps unfortunately, the series of lectures, for the introduction of which, as previously mentioned, Aikin was responsible, gradually died out. Aikin himself had no successor among the officials able and willing to devote himself to popular exposition, though Scott Russell had all the capacity for such work had he cared to undertake it. And so after Aikin's time the Society, less fortunate than the Royal Institution, found no Faraday to draw intelligent audiences to its meeting-room by brilliant expositions on the applications of science and art, and it really was not until the receipt of the Cantor bequest enabled the Society to provide courses of lectures that this valuable means of diffusing knowledge on industrial subjects was utilised. There was, however, no very great difficulty in securing suitable topics or capable authors for filling up the programme for the Wednesday evening meetings, and this important portion of the Society's labours rapidly developed, and eventually became its principal duty.

But if the regular routine of the Society's work was thus provided for, there were many outside objects to which the Council now began to direct its attention. In this they were very greatly helped by the fact that they had as the Society's President the Prince Consort, who assisted them not only by his influence, which at the time was naturally much less powerful than it became in later years, but by the interest which he took in, and the attention which he devoted to, the Society's affairs during the first years of his Presidency. He realised—and he himself told the Society—that the main object of its existence was the application of science and of art to industrial purposes. These were matters in which he took a genuine personal interest, and so long as the Society was ready to promote the objects he had at heart, he was quite willing to assist it as far as the numerous other occupations of his exalted position allowed him sufficient leisure. It has often been said that too much credit has been given to the Prince Consort for the Society's success about this time, especially for its success in starting the 1851 Exhibition, but a careful study of the Society's records has satisfied the present writer that this influence was by no means exaggerated. It is quite clear that the Prince did not initiate the reforms—economic, social, and industrial—which started from the Society of Arts. But most new suggestions of any importance appear to have been submitted to him, and he discriminated with extreme shrewdness between those which were of value and those which it was not worth while to press. He evidently had an extremely quick and active mind. His judgment on the questions submitted to him seems generally to have been prompt and correct, and this is surely as much as can reasonably be looked for from one occupying a position such as he occupied. The period on which we are now engaged may justly be considered as the period of his Presidency, and we may have a little more to say about the value of the services he rendered the Society when we come to deal with the termination of that Presidency by the Prince's death in 1861.

During that period by far the most important of the public works carried out by the Society was the starting of the two great Exhibitions of 1851 and 1862. The history of these two Exhibitions, so far as the Society was associated with them, has been sufficiently dealt with in two articles by the writer, which appeared in the *Journal* some years ago.* The next most important piece of public work was the establishment and organisation of a system of examinations carried out simultaneously all over the kingdom, which had the very greatest influence on industrial, middle-class, and scientific education during the fifties and sixties. For an account of this work reference may be made to a previous article in the *Journal*,† and consequently nothing need now be said, either of the two Exhibitions or the examinations. This article will, therefore, be devoted to the consideration of the various other matters which

* "The Early History of the 1851 Exhibition," *Journal*, Vol. XLIV. p. 889 (November 6th, 1896); "The Society of Arts and the 1862 Exhibition," *Journal*, Vol. XLV. p. 80 (December 18th, 1896).

† See footnote, p. 1013.

the Society had in hand during the period which extended from the date of its charter (1847), or the assumption of the Presidency by Prince Albert (1843), down to the date of the Prince's death (1861) and the holding of the second great Exhibition in 1862.

The subjects pursued by the Society during this period were so diverse and so numerous, that it is not at all easy to give any connected history of its proceedings. Perhaps, when those who had in hand the reconstitution of the Society realised that the purpose of its original institution had been served, and that some other methods must be devised for carrying out the objects of its foundation, they found it difficult to set a limit to the scope of its work, and the result was that they extended its operations a good deal beyond what was intended or contemplated by its original founders, somewhat, indeed, beyond what was intended by the framers of its charter.

The newly-constituted Council was a strong body, and the very fact that it was newly-constituted made it anxious to effect reforms, not only in the Society itself, but in all the departments of public life and administration with which the Society could, by any reasonable extension of its objects, claim association.

The Council, as a body, was quick to realise the value of the Society's organisation as an instrument for the promotion of many useful social and economic as well as industrial changes. Many of its members were active-minded, energetic men, keenly interested in the promotion of special reforms, full of enthusiasm for the causes they had espoused, and anxious to utilise the growing influence of the Society for the realisation of their own particular objects.

Prominent among these was Henry Cole, a man of exhaustless energy, full of enthusiasm for his own ideals and of confidence in their value. At the instance of Scott Russell he joined the Society in 1846 and at once became a member of the Committee of Fine Arts. In January of the following year we find him attending a meeting of the Council, to explain, as a representative of the committee, the scheme he had laid before them for annual exhibitions of the work of British artists, and suggesting as a commencement an exhibition of the works of Landseer, then at the height of his popularity. In the same year (1847) he was nominated for the Council, and from that time till the date of his death, in 1882, he continued to exercise the strongest personal influence over the Society, influence which, for the first half or so of this period, really amounted to absolute control. A man of singularly active mind, he was perpetually conceiving fresh projects for the improvement of public welfare and the benefit of mankind. Some of these were eminently successful, such as the Victoria and Albert Museum, and, it may be said, the 1851 Exhibition, since, if he did not originate the idea of a great international exhibition, it was his capacity for organisation that rendered the scheme practicable. Others naturally enough were failures, but the bulk of his proposals were valuable, and of genuine public utility. With very nearly all the Society of Arts was associated. He utilised its influence and its organisation to the full, and he repaid its help by useful guidance and administrative direction.

He was not a skilful financier. Certain of his schemes cost the Society dear, but if he wasted some of its funds, it was mainly due to him that the Society had any funds to waste. It is the matured opinion of the writer, who knew him well and admired his great qualities, without being in the least unaware of his faults, that Henry Cole ought to be looked on as the second founder of the Society, and that it was owing to his influence and authority that the Society was raised from a state of impotence and insignificance to a condition of prosperity and influence. This does not imply that he started the improvement. He did not. The Society had been rescued from dissolution before he became a member of it; but he infused fresh vigour into its growth, and in a few years from his joining its governing body it had trebled the number of its members and quadrupled the amount of its funds.

It may be admitted that Cole had in full measure the defects of his qualities. He liked having his own way, and he generally got it. He disliked opposition, and was ruthless with his opponents. He was a born fighter, and his methods of fighting were often questioned and disliked. Naturally enough, this made him unpopular, while the objects he sought often laid him open to the ridicule which is generally the lot of those who first advocate schemes for the accomplishment of which others in a later age are hailed as the benefactors of their kind. However, he cared little for ridicule or for unpopularity, so long as he got what he wanted, as he usually did. His best friends and admirers must wish that he had had greater regard for the feelings of others, and that he had been content to attain his objects without thrusting aside and trampling over those who did not agree with him. But that was not his way, and

Hosted by Google

perhaps, gentler methods might have proved less successful. At all events, it is likely that they would have been slower, and of all things, delay was hateful to the impatient soul of Henry Cole.

Of course, he had a fight soon after he joined the Council, and, unhappily, it was with one of the best and staunchest friends of the Society, Thomas Webster. Webster, doubtless disapproving of Cole's arbitrary methods, and his somewhat reckless expenditure, opposed his proposals for annual exhibitions, industrial and pictorial. His criticisms were supported in the Council, and, in 1850, Cole resigned. But he organised an opposition at the next annual meeting, and circularised the members, with the result that at a largely attended meeting on April 3rd, 1850, when 207 members voted, Cole and his friends were elected by a considerable majority, while Webster and his supporters were turned out. Inasmuch as it was Webster who, by the introduction of much-needed reforms, had saved the Society from certain dissolution in 1842,* the vote of the electors appears ungracious, especially as bitter feeling was engendered by it. But, as above said, those who got in Henry Cole's way generally had to get out of it. His differences with Webster are the more to be regretted as Webster had the scientific knowledge to which Cole never made any pretensions, and his experience as a great patent lawyer might not improbably have led the Society to take a larger part in the guidance of industrial progress and the application of science to manufactures than it really did take.

Cole was Chairman of the Council in 1850, and again in 1852. One of the most prominent of his successors was Wentworth Dilke, who was Chairman in 1857 and 1858. He took an active share in the arrangements for the two great Exhibitions of 1851 and 1862, and a baronetcy was conferred upon him on the close of the Exhibition of 1862. He was so keen about the Society's welfare that he brought his relations into it. His father, the well-known editor of the *Athenæum*, became a member of the Society in 1849—Dilke himself having joined four years earlier—and he made his two sons, Charles and Ashton, life members when they were boys. Another very energetic and capable Chairman was Sir Thomas Phillips, who succeeded Dilke, and was found so useful in the post that the by-laws were altered so as to allow him to hold the Chairmanship for four consecutive years, 1859 to 1862. Sir Thomas Phillips was a man of some character. He earned his knighthood by his action in quelling a Chartist riot in a mining district of South Wales, when he was wounded. He was a liberal and public-spirited man. Besides devoting himself strenuously to the Society's work, he took an active part in the work of King's College and many metropolitan societies.

* *Journal*, April 5th, 1912, p. 537.

Another most useful member was Harry Chester, who was Chairman in 1853. He was the originator of the Union of Mechanics' Institutions and of the Society's examinations, and continued an active worker on behalf of the Society until his death in 1868. He held certain official appointments, including the Assistant Secretaryship of the Committee of Privy Council on Education. The public work he did, mainly through the Society of Arts, never received due recognition; he is even ignored by the "Dictionary of National Biography." Lieut.-Colonel Owen was elected Chairman in 1853, but was compelled by pressure of his official work to decline office before actually taking any active part in it. But he was in many respects a useful member of the Council, and took his full share of its work. He was a brother of Sir Philip Cunliffe-Owen, who in later years was closely associated with the Society. The Rev. James Booth became Chairman in 1855. The work he did in suggesting the establishment of the Society's *Journal*, and in the development of its examinations, will be referred to later on.

Other Chairmen of Council during this time were Colonel W. H. Sykes, M.P., F.R.S. (1856), Chairman of the Board of Directors of the East India Company; Lord Ebrington (1854), afterwards Earl Fortescue, who lived and preserved his interest in the Society until 1905; and William Saunders, F.R.S. (1851), a naturalist of some note in his day, who wrote much on botany and entomology, and served as President of the Entomological and Horticultural Societies.

Amongst other members of the Council who took a prominent part in the Society's work, and attended most constantly at its meetings, the following should be mentioned: Dr. Lyon Playfair (afterwards Lord Playfair), the eminent chemist; Richard Redgrave, R.A., and his brother Samuel, the author of the useful Dictionary of Artists of the English School; Sir Joseph Paxton, who designed the 1851 Exhibition building; Robert Stephenson, the great engineer; Richard Dawes, the Dean of Hereford, who gave valuable help in organising the examinations; J. C. Macdonald, the manager of the *Times;* Sir W. H. Bodkin, the eminent

Hosted by Google

lawyer, who co-operated with Thomas Webster in the reform of the Society; Thomas Graham, Master of the Mint; William De la Rue, F.R.S.; Sir John Pakington (afterwards Lord Hampton); Sir William Page Wood (afterwards Lord Chancellor Hatherley); J. J. Mechi, the enthusiastic agriculturist; Sir William Fairbairn, the engineer, who was a commissioner for the 1851 and 1862 Exhibitions, and took a particularly active part in the organisation of the latter; Thomas Winkworth, a man not much known outside the Society, but one who did much hard work within it for the Exhibitions and other matters; Thomas Twining, the earnest advocate of many philanthropic schemes; Joseph Hume, the Radical M.P. and economical reformer; Sir John Boileau, an archæologist of repute; and William Tooke, for many years a Vice-President, and the Society's honorary solicitor.

These were among the most active supporters of the Society. Something may now be said about the permanent officials. In the early part of the period with which we are now concerned, the office of Secretary changed hands rather frequently. In the ten years, 1843–53, there were six occupants of the post. As previously mentioned,* when Graham retired in 1843 (after holding office for two years only), Wishaw was appointed, and in 1845 he was succeeded by John Scott Russell. Scott Russell was a worthy successor to Templeman and Aikin, and, indeed, as a scientific man he was superior to either. Born in 1808, he was thirty-six years of age when he came to London, and became a member of the Society of Arts. He had already acted as Professor of Natural Philosophy at Edinburgh, and had acquired a reputation for his original researches on Wave Motion. He had also carried out, with much success, the construction of several large vessels in which his principles were embodied. These were all designed by him as manager of the shipbuilding establishment at Greenock, afterwards belonging to Messrs. Caird.

Before his election as Secretary, he had taken an active part in the deliberations of the Committee on Miscellaneous Matters. Though he was too active-minded to confine his attention to the Society's work, he made a most efficient and energetic Secretary, and took his full share in the work of reconstructing the Society, which may be said to have been completed during his term of office. The steady improvement in the character of the papers brought before the evening meetings was certainly to a large extent due to him. He seemed ever ready to place at the disposal of the Society not only his abilities, but what he had in much less abundance, the contents of his purse; for he frequently took upon himself the provision of expenses which assuredly he was not called upon to meet, and which, indeed, he could not properly afford.

His energy in helping on the preparations for the 1851 Exhibition led to his being appointed, jointly with Mr. Stafford Northcote (afterwards Lord Iddesleigh), Secretary to the Royal Commission when it was appointed in January, 1850. After this he resigned the Secretaryship of the Society, and, having been elected a life member, was placed on the Council. In later life he resumed the practice of his profession, with a result that cannot be better stated than in the words of the author* of the account of his life in the *Proceedings of the Institution of Civil Engineers*—

"In summing up Mr. Scott Russell's connection with the profession of naval architecture, it may be said that on commencing his career he found it the most empirical of arts, and he left it one of the most exact of engineering sciences. To this great result many others contributed largely besides himself; but his personal investigations, and the theories he deduced from them, gave the first impetus to scientific naval architecture." †

A man of real genius, he took high rank in his profession, among a race of great engineers, and in his own particular branch of it he was far ahead of his contemporaries. But, spite of his great talents, his worldly success was never equal to his deserts, and when he died in 1882 it was in straitened circumstances.

Scott Russell's successor was George Grove, who was appointed jointly with Russell in February, 1850, and, after a month's trial, sole Secretary in March. Grove, like his two predecessors, was an engineer, and he had practised his profession to some extent before his appointment, though never afterwards. His tenure of office was very short, for when the Crystal Palace was established at Sydenham he was (in May, 1852) offered the appointment of secretary, and thereupon he gave up his post at the Society. He was a thoroughly capable official—in this respect superior to his immediate predecessors, and with a longer period of service he would, doubtless,

have left his mark on the administration of the Society. As it was, his powers were devoted to other institutions—first the Crystal Palace, and afterwards the Royal College of Music—where they had full scope and were greatly appreciated. Grove was the last Secretary to live on the Society's premises. When he quitted office the house in which all the Secretaries since Templeman had lived, and in which two of them (More and Taylor) had died, was added to the Society's offices.

When Grove retired, Edward Solly, long an active member of the Council, was appointed Secretary, and held the office for a year—May, 1852, to May, 1853. Solly was an old and active member of the Society. He had been elected in 1838, and had served on the Council since 1850. At the time of his appointment as Secretary he was actually deputy-chairman. He was a chemist of some reputation. He became a Fellow of the Royal Society in 1843, and in 1845 was appointed Professor of the Addiscombe Military College. He resigned that he might devote himself to the organisation of the Trade Museum started by the Society, of which more hereafter. Though not a man of brilliant talent, he possessed considerable intellectual powers and some literary capacity, which he devoted in later life principally to antiquarian and bibliographical subjects. He died in 1886.

Solly was succeeded in the Secretaryship by Peter Le Neve Foster, whose genial and kindly nature gained him the regard and esteem of all those with whom he worked. He is still remembered by many of the older members of the Society; by none outside those of his own family can his memory be more affectionately cherished than by the writer of these notes. He, like his predecessor, had for some years been connected with the Society, which he joined in 1837, at the instance of his grandfather, Abraham Osorio, who had become a member in 1800. His father (also Peter Le Neve) joined the Society in 1807, so that he had a long family connection with it. When the first Council was formed, he became an *ex officio* member of it, as he was at the time Chairman of the Committee of Accounts. He was at once elected treasurer, and this office he held till 1852, when he became an ordinary member of the Council.

Foster took his degree in the Mathematical Tripos of 1830, and became a Fellow of his college (Trinity Hall). In 1836 he was called to the Bar at the Middle Temple, and he practised as a conveyancer until his election to the secretaryship, which he held for a period of not quite twenty-three years, till his death in 1879. He had taken his full share in the reorganisation of the Society, and by the time that he became Secretary its various difficulties had been surmounted, and its second era of prosperity had commenced. This prosperity continued unabated during his term of office, and much of the credit for this state of things may fairly be claimed for him.

If he did not originate any changes or introduce many fresh ideas, he carried out efficiently and well all the executive work of the Society, and it may fairly be said that its public reputation for sound practical work stood a good deal higher at his death than it did when he became secretary. Possessed of much sound scientific knowledge, of wide general reading, and endowed with considerable intellectual capacity, he was well qualified for the duties of his office, for which also he was well fitted by character and taste. Of a kindly genial nature, singularly patient and forbearing, tactful and full of common sense, he made an admirable Secretary. If he was devoid of ambition and inclined to be somewhat "easy-going," this only made him more contented with his duties, and never induced him to neglect them, for he was a steady and regular worker, who took a pleasure in his work.

He had various interests outside the Society. Among the first to practise, as a scientific amateur, the art of photography, he was one of the founders of the Photographic Society, and for many years on its Council. He followed with interest the developments of the art during its most interesting period, from the first photographic application of collodion, to the introduction of the gelatine dry plate, and wrote a good deal on the subject. At one time he served on the Council of the British Association, and was for thirteen years secretary of Section "G," Mechanical Science.*

Some reference is also due to certain of the other officials of the Society. Of these Samuel Thomas Davenport comes first, both from his seniority and because he devoted his whole life to the Society's service.

His appointment in 1844 as a sort of clerk or assistant to Wishaw has been mentioned,† and from that date he served the Society faithfully and well in various capacities, being always

* The fullest account of P. Le Neve Foster will be found in the notice published after his death in the *Journal*, Vol. XXVII. p. 316. There is also a short life in the "Dictionary of National Biography."

† *Journal*, April 5th, 1912, p. 158.

Hosted by Google

ready to undertake any work that might be required of him. His pay was very moderate, and occasionally small grants were made to him, which were certainly well deserved. In April, 1848, he was given the title of assistant secretary, and in January of 1849 his salary was made up to £100 a year. Six months later W. Ellis was appointed assistant secretary, but he only held office for less than a year, as he resigned in March, 1850, when the office was left vacant. Davenport was then made "Curator and Collector," at a salary of £150, and in 1853 his title was changed to that of "Finance Officer," afterwards modified to "Financial Officer," an appellation which he bore, with much personal pride and gratification, till his death in 1876. It would not be easy to overrate the value of Davenport's services to the Society, though they were in the earlier part of his life of an unpretending nature. Later on, his very considerable experience, and his minute knowledge of the Society's history, gave him much influence with the Council, and his opinion in matters connected with the internal administration of the Society carried great weight. He had had in youth some artistic training, and would have made a capable engraver had he followed the profession for which he was intended, but in other subjects he was mainly self-educated. He had acquired a curious and extensive knowledge of the contents of the Society's records, and this led him to produce, in the form of a paper read at one of the meetings in 1868, a short history of the Society,* which has before been referred to in this series of articles. Though it contains much information, it is badly put together, and shows a want of literary skill. The same criticism may be applied to his other communication to the Society, on "Prints and their Production,"† though it has a distinct value as recording much which is not to be found elsewhere about the earlier attempts to produce printing surfaces by means of photography, since at the date of the paper many such attempts had been made, but none had yet succeeded.

His single-minded and whole-hearted devotion to the interests of the Society rendered him a zealous and valuable official. The present writer who, of course, knew him intimately during the last eleven years of his life, and had for him a genuine liking and regard, can testify to the kindliness of his nature and to his popularity amongst those with whom he was associated.*

From the date of Ellis's resignation in 1850 to the middle of 1852, the office of assistant secretary was left vacant. In June of that year James Forrest, who had previously been assistant secretary to the Institution of Civil Engineers, was appointed. He held office till April, 1856, when he resigned, in order that he might return to his old office at the Civil Engineers, with a view to his succeeding Charles Manby, who was about to give up the secretaryship of the Institution. This arrangement was duly carried out, and Mr. Forrest was appointed in 1860. All engineers know with what credit to himself, and with what benefit to the Institution, he filled his office, till he resigned in 1896. His name will always be associated with the Institution by the Forrest Lectures, founded to commemorate his secretaryship. Mr. Forrest is still living in retirement at St. Leonards, now one of three surviving representatives of the Society of Arts of sixty years ago.

It was determined to fill up the vacancy caused by Forrest's retirement by an open competitive examination, the time being one when the value of test examinations ranked higher than it does now after half-a-century's experience. Accordingly, the appointment was advertised, and the candidates who applied were submitted to a regular examination, both viva voce and by papers. Charles Critchett, who had taken his degree at Cambridge (Trinity) in 1855, was successful, and he was duly appointed. It must be said that the experiment was quite successful. Critchett made a perfectly efficient assistant secretary for thirteen years. He resigned of his own accord in 1869, though his connection with the Society was preserved by his appointment as educational officer, in which capacity he had a nominal responsibility for the conduct of the examinations. He held this office till 1879, and when he gave it up he was made a life member. As he was quite comfortably provided for there was no need for him to work, and he naturally enough preferred a life of leisure to a continuance of official routine. He was a man of artistic tastes, cultivated manners, fond of society, and popular in a large circle of friends. He died in 1906.†

Having dealt with the principal individuals who carried on the Society's work during the

* *Journal*, Vol. XVII. pp. 10, 127, 143, 160. He had previously (in 1864) read a paper on the Society's promotion of industrial education, *Journal*, Vol. XIII. p. 88.

† *Journal*, Vol. XVIII. p. 62. The paper had been preceded by an article on the same subject in the *Journal*, Vol. XIII. p. 131.

Hosted by Google

period which began with its incorporation and ended with the 1862 Exhibition, we may pass on to a consideration of the work itself. At the commencement of the period, the attention of the Council was chiefly occupied with the organisation of the first great exhibition, and during its last years with the preparations for the second; but in spite of this, time was found for a great variety of other business, the chief items of which have now to be described.

Of these, the most important was education, industrial education as it was then termed, though by this was meant the general education of those engaged in industry, not what we now know as technical education, the training of industrial workers in the subject matter of their trades.

The first efforts for the promotion of popular education in this country took the form of the establishment of Mechanics' Institutions. Their origin may be traced as far back as 1800, when Dr. Birkbeck, who had succeeded Dr. Garnett as Professor of Natural Philosophy at the Andersonian University of Glasgow, established courses of lectures, to which working men were admitted at a low fee. The mechanics' classes thus established were for a long time a successful department of the University, and in 1823 this department became the Glasgow Mechanics' Institution, apparently the first genuine institution of the sort.

The establishment of this institution suggested the formation of a similar organisation in London, where Dr. Birkbeck had been resident for about twenty years. He took the lead in the movement, and, with the assistance of Lord Brougham and others, established the London Mechanics' Institution, which later on became the well-known Birkbeck Institution, the name being changed in honour of its founder and first president.

The London and Glasgow Societies had many imitators, and in 1848 the Society passed a resolution that any such institution established not less than fifteen miles from London might join the Society for the same subscription as an individual, so that its members might enjoy, under certain conditions, the advantages of membership of the Society. A few institutions availed themselves of the offer, and a little later, in 1851, Mr. Harry Chester addressed a letter to the Council, suggesting that "the Society should exert itself to increase the efficiency of the metropolitan and provincial mechanics' institutes." The result of this letter was that the Society called together a conference on the subject, which was held in May, 1852, under the presidency of the Earl of Lansdowne. At this conference a union of institutions was suggested, and such a union was formed in the following July by a resolution of the Council. The object of the union was to enable the scattered institutions to co-operate, and thereby to increase their educational facilities. The intention of the Society was to provide a central organisation, from which information could be distributed to the institutions, lists of lecturers provided, and other facilities for their development arranged.

In addition to holding this conference, the Society issued, in 1853, a long report on "Industrial Instruction," which had been prepared by a committee appointed for the purpose. This committee took a great deal of evidence from schoolmasters, manufacturers, representatives of mechanics' institutions, and others, and the information they supplied forms the principal and the most valuable part of the report.

It was determined to hold an annual conference for the discussion of subjects relating to the institutions and their organisation, and such a conference was held at the Mansion House in May, 1853, by the then Lord Mayor, Mr. Thomas Challis, at the request of the Society, by which time 270 institutions had joined the union. In connection with this conference a small exhibition of educational appliances was held in the Guildhall, and this led to a proposal for a similar exhibition on a larger scale to be held in the following year, the centenary of the Society. The proposal was readily taken up. Prince Albert expressed his warm approval of it, and promised a subscription of £100. The accommodation on the Society's premises being quite inadequate for an exhibition on the scale proposed, St. Martin's Hall—a large concert hall, which had been built for John Hullah in Long Acre — was taken for the purpose.*

The exhibition proved to be a great success, and quite justified the very considerable amount of labour which was expended upon it by the Council. Contributions (through the assistance of the Foreign Office) were secured from France, Belgium, Holland, Sweden, Norway, Denmark, Austria, Prussia, Switzerland, Spain, and the United States. The exhibits included educational apparatus and appliances of all sorts,

* St. Martin's Hall was built in 1847–1850; it was No. 89, Long Acre. It was burnt down in 1860, and its destruction nearly ruined Hullah, who had invested most of his money in it. Later on, the Queen's Theatre was erected on the site, which is at present occupied by private premises.

Hosted by Google

school buildings (shown in plans and models) and fittings, books, maps, etc., together with samples of work produced at schools. It was opened in July, 1854, by Prince Albert, and remained open until September. Arrangements were made for the delivery of lectures by the most eminent authorities on Science and Education. The list of lecturers included Dr. Whewell, Professor De Morgan, Dr. W. B. Carpenter, Dean Trench, Cardinal Wiseman, Professor Alexander Williamson, Professor Huxley, Dr. Hullah, and many other names of almost equal renown.*

Including the donation from the Prince Consort, the subscriptions amounted to £1,079. This involved a pecuniary loss of £363, which was made good by the Society. The success of the exhibition led to the suggestion that it should be made permanent, and this view was impressed by the Council upon the Government, with the result of the foundation of the educational collection and library at South Kensington as part of the Museum, now the Victoria and Albert Museum. A great number of the exhibits were presented to the new Museum, and formed the nucleus of the educational collection, and also of the fine library forming part of the Victoria and Albert Museum.

The conference of representatives of institutions became an annual function, and was continued regularly on the same day as the annual dinner, so long as the dinner was held. It lasted for a little over twenty years, until 1875, by which time its usefulness had quite passed away. In the following year it was changed into a special conference on Adult Education, at which Sir Henry Cole presided, and in 1877 its place was taken by a conference on Domestic Economy, held at Birmingham, at the suggestion of the same gentleman, who had by that time retired from the public service, and was then temporarily resident in Birmingham. After that the conference was allowed to lapse.

It would, indeed, have died out long before, but for the institution of the system of examinations, which has now for over fifty years been a very important part of the Society's work. It was in December, 1853, that Mr. Harry Chester, the founder of the Union, suggested the establishment of a system of examinations for the benefit of members of the affiliated institutions. The proposal was much discussed in the Council, by special committees, and at the meeting of the conference. It was at once generally approved, but it took some time before a satisfactory scheme could be evolved. A very strong board of examiners was appointed, and at first the control of the examinations was left in their hands. Divergent views soon made themselves evident, and there was some friction between the Board and the Council. Eventually, however, these matters were satisfactorily arranged, and a system devised for the concurrent holding of examinations at appointed centres all over the kingdom, a system which has not only worked well and smoothly for the Society's own examinations, but led to the larger system of examinations by the Government Department of Science and Art, and a little later to the University Local Examinations. It is unnecessary to say more here about the history of the examinations, because it has been dealt with in sufficient detail in a previous article in the *Journal*, which, originally contributed in the form of a paper by the present writer to the proceedings of the International Congress on Technical Education, held in London in 1897, has since been republished with additions in the *Journal.**

Probably the real value of the Union of Institutions was that it encouraged the establishment and development in provincial towns of educational organisations, which a little later provided suitable centres for the local science and art schools, and thus served as a basis for the whole system of education, scientific, artistic, and technical, which has grown up around those schools.

When the Society took in hand the organisation of local institutions some of them were flourishing and doing serious work, but many others were in a feeble condition. Such education as these latter afforded was of a trivial sort, and they were devoted rather to amusement than to instruction. The Society provided a standard to which all were expected to conform, and a central organisation from which all could get information and help.

After some twenty years or so the work of the Union was done, and there was no longer much need for its existence. When in 1882 the examination system was remodelled, and the examinations were thrown open to everybody, the last reason for its maintenance disappeared, and though there are still a few institutions which like to preserve their old association with the Society, it must be admitted that the

* Some of these lectures were published in a volume (Routledge, 1855). Others were reported, more or less fully, in the *Journal*.

* *Journal*, April 16th, 1909, Vol. LVII. p. 431.

Hosted by Google

practical advantages they derive from that association are now inconsiderable.

It was the existence of the Union of Institutions that led to the establishment of the Society's weekly *Journal*. The first suggestion of such a thing was made by the Rev. Dr. Booth, in a letter which he addressed to the Council in June, 1852. In this letter he set out in considerable detail the scheme of a weekly newspaper which should record all the Society's proceedings, serve as a medium of communication between the Society and the allied institutions, and form a permanent record of the progress of science, art and industry. The proposal had evidently been thoroughly well thought out, and was, indeed, eventually adopted without any considerable modifications.*

As mentioned in a previous article of this series,† the *Transactions* of the Society had stopped in 1844, and from that time there had been no regular record of the Society's proceedings. The occasional publication first known as the *Abstract of Proceedings*, and afterwards, when it got to be published with greater regularity during the session, entitled *Weekly Proceedings*, had increased slightly in size, and it, at all events, recorded in brief abstract the papers read before the Society, and gave some amount of information about its other proceedings. This from 1844 to 1852 was the only publication regularly issued by the Society, for the odd volume of *Transactions* published in 1852, and intended to form the first of a new series, had no successor, and can only be regarded as an unsuccessful experiment, as it proved too costly for repetition. A volume issued in 1851, and entitled Vol. LVII. of the *Transactions*, is really nothing more than the weekly proceedings for the year bound together. Even the meagre record preserved in the *Weekly Proceedings* would not now be available but for the care of Davenport, who in November, 1852, presented to the Council a "volume containing a complete set of the papers published in the years 1844–9, during which time no regular transactions were published, and consequently no record of the Society's proceedings existed."‡ Davenport had no doubt carefully preserved a copy of each issue, which nobody else seems to have done, and his volume is the only set of them in the Society's possession.

Booth's suggestion commended itself to the Council, and after some discussion and consideration, it was accepted, the form of the *Journal* settled, and its regular publication commenced, the first number appearing on November 26th, 1852. This number, after a preliminary notice dealing with the proposed scope and character of the new publication, contained the address of the chairman (Henry Cole) at the opening meeting of the Session, an interesting account of the Industrial Societies of the United States, one of the replies (from British Guiana) to a circular asking for information about the productions and commerce of the Colonies; reports of the proceedings of many of the affiliated institutions, and a list of applications for patents under the new Patent Law Amendment Act of 1852. There are four pages of advertisements, but three of those are Society's notices. Succeeding numbers contain the papers read at the ordinary meetings—at first in abstract, and afterwards in full—with brief notes of the discussions, reports and notices dealing with the various matters on which the Council and the numerous committees were engaged, and much miscellaneous information on subjects connected with the objects of the Society. From the first the *Journal* was a newspaper, and was stamped with the newspaper stamp required at the time. This duty on newspapers was originally imposed by the Stamp Act of 1712, and, after several reductions, was finally abolished in 1853.

When the accounts of the 1851 Exhibition had been made up, it was found that there was a surplus profit of £186,000. Of this, however, £67,896 was the amount which had been subscribed before the Exhibition was started, and it was expected that this would be returned to the subscribers, or at all events given back to the various localities in which it had been subscribed. The Society, which had collected the money, also put in a claim for a share. However, it was decided that the money should be kept, and used for the foundation of a central institution "for the dissemination of a knowledge of science and art among all classes."

This caused a good deal of disappointment at the time, but, looking back at all the circumstances, it cannot be doubted that the decision was a wise one, and that better results have been obtained than if the money had been

* The Rev. James Booth, LL.D., F.R.S., was at this time Vicar of Wandsworth. His suggestion led to his being elected on the Council (1852), and he afterwards (1855) became its chairman. He took a very active and useful part in the establishment of the examinations, but later on some friction arose between the Council and himself, and after a quarrel, the details of which are certainly now not worth recording, he was called upon to resign his seat on the Council, and did so. He died in April, 1878.

† *Journal*, April 5th, 1912, p. 531.

frittered away by distributing it in comparatively small sums for provincial objects. Eventually, as is well known, the estate at Kensington Gore was purchased, and the 1851 Commissioners were formed into a permanent body for its administration. Many schemes were proposed and discussed. Prince Albert had a large and comprehensive scheme of his own, which included the erection of suitable buildings, and the transplantation of the principal learned societies to South Kensington. The idea was a fine one, and if it could have been carried out we might perhaps have had, years ago, a single comprehensive board or institution for dealing with education, science and art, instead of our present system, which, whatever its merits, cannot claim to be a model of organisation, economy or uniformity.

But there was much opposition, and there were many difficulties. The story is too long for repetition here. Those who care may find much of it in Sir Henry Cole's Life. It may be sufficient to say here that the immediate outcome was the South Kensington Museum and the Science and Art Department, with the foundation of both of which the Society had much to do.

The second report of the Commissioners of the 1851 Exhibition, published at the end of 1852, and reporting the purchase of the Kensington estate, referred, amongst other matters, to the formation of a trade museum, and invited the co-operation of the Society of Arts. The Council at once took the matter into consideration, and the result was that in May, 1853, they offered to undertake the formation of a collection of animal products used in manufactures, and to devote to it a sum of £400, to be expended in the course of two years, if the Commissioners would provide a similar amount. This was at once agreed to, and the formation of such a collection immediately put in hand. Professor Solly undertook its formation, and for that purpose resigned the secretaryship of the Society. He devoted himself energetically during the following two years to the work, and the result was that in May, 1855, a very complete collection was exhibited in the model room, and was formally opened by the reading of a paper by Mr. Solly. The exhibits fully illustrated the utilisation of animal products for industrial purposes, and comprised textiles (wool and silk), leather and furs, horn and bone, bristles, feathers, hair and shell, also wax and lac, oils, and, finally, refuse materials.

The collection, after being for some time exhibited by the Society, was made over to the Science and Art Department, and was placed in the South Kensington Museum, which was opened, in the temporary buildings for long known as the "Brompton Boilers," in 1857. As is well known, the original intentions of the 1851 Commissioners as to the formation of a trade museum were never carried out. The collection of animal products was transferred to the Bethnal Green Museum, when, new buildings having been built for the South Kensington Museum, the old "boilers," with certain additions, were re-erected at Bethnal Green.

The total amount expended by the Society, including the £400 originally granted by the Commissioners, was £976. On the transfer of the collection, the Commissioners agreed to repay the Society's expenditure, and the balance (£576) was accordingly repaid to the Society.

This collection and the educational collection previously mentioned were the chief contributions of the Society to the Museum. Both of them were valuable, not so much for themselves, but because they formed a nucleus out of which, by continual accretions, the scientific and educational collections now forming part of the Victoria and Albert Museum have grown. It must, of course, be understood that this does not refer to the Art Museum, to the contents of which the Society was never in a position to make any but trifling contributions.

As regards the Science and Art Department, the Society can only claim the credit of having done a good deal of pioneer work, and of having prepared the way for its establishment. Though Schools of Design* were started in 1839 or 1840, they were, by all accounts, not very successful, and in 1851 a vigorous attempt was made by the Society to encourage the formation of such schools on an independent basis. The proposal was well taken up in several provincial towns and in London, but in the following year the Department of Practical Art was formed by the Board of Trade, and this a year later became the Science and Art Department. It took over the existing Schools of Design, and there was no further need for the Society to persevere with its scheme, which was accordingly dropped.

Still more useful service was rendered the new Department by the Society's development of Mechanics Institutions and by its examinations. It was at these institutions that the

* They were not really Schools of Design at all. They were called so because they were imitations of the French *Écoles de Dessin*, and were simply, like the French originals, drawing-schools.

Hosted by Google

Science Schools and Art Schools were first formed, and it was on the model of the Society's examinations that the much larger scheme of Government science examinations was carried out.

Before the opening of the 1851 Exhibition the Council announced the offer of prizes for essays or treatises on certain sections of the Exhibition. But before the time came for the award of these prizes, Prince Albert, in the autumn of 1851, suggested that a series of lectures should be given at some of the Society's meetings, "on the probable bearing of the Exhibition on the various branches of Science, Art, and Industry." This proposal was at once adopted, and the offer of prizes withdrawn.

In all twenty-four lectures were delivered during the session 1851–2,* and these were afterwards published in two volumes, which attained a considerable amount of popularity. The first lecture was given by Dr. Whewell, at the opening meeting of the session in November, 1851, and dealt with the general bearing of the Exhibition on the progress of Art and Science. Among the other eminent lecturers were Sir Henry de la Beche, on Mining, etc.; Professor Owen, on Raw Materials; Dr. Playfair, on Chemistry; Dr. Lindley, on Food Substances; Professor Willis, on Machines; Professor Royle, on the Arts and Manufactures of India; Sir Thomas Bazley, on Cotton; and Digby Wyatt and Owen Jones, on the Decorative Arts. The concluding lecture on the "International Relations of the Exhibition" was given by Sir Henry Cole.

Of the various exhibitions which were held by the Society in its own house many were the forerunners of the 1851 Exhibition, and it was out of them that the Great Exhibition eventually evolved itself. Reference has been made in a previous article to the announcement made in 1846 of prizes for designs "for useful objects calculated to improve general taste." This announcement was the result of an offer of £50 made "through the secretary" to the Council at its first meeting. As a matter of fact, the offer was made by Scott Russell himself. It has also been recorded how one of the articles sent in was the tea service designed by Henry Cole, and submitted under his well-known pseudonym of "Felix Summerly," which was manufactured, at his instance, by Messrs. Minton. It is because this offer of prizes led to the first exhibition of British manufactures, and because this first exhibition gradually led up to the 1851 Exhibition, that it has been said that "Felix Summerly's" teacup was the origin of the Exhibition.

The response to the first offer of prizes was but meagre. Nevertheless, it was renewed in the following year (1847), and it was the prize articles of 1846, together with the articles sent in in competition in 1847, which formed the basis of the Society of Arts' first exhibition of "select specimens of British Manufactures and Decorative Art," which was opened at the Society's house in March, 1847. The exhibition itself would have been but a poor one had it not been supplemented by examples lent at the urgent solicitation of Henry Cole, Scott Russell, and another member of the Society, who, as Russell himself afterwards said, spent three whole days travelling about London in four-wheel cabs calling on manufacturers and shopkeepers, till they had at last succeeded by personal entreaty in inducing some of them to send sufficient goods to fill the exhibition room. In the event, however, the exhibition turned out a complete success, and it was visited by 20,000 people. Still greater success attended a repetition of the experiment in 1848, for manufacturers began to realise the advantage of the cheap advertisement provided by exhibitions. This second exhibition was attended by over 73,000 visitors, and for the third, in 1849, the accommodation on the Society's premises proved quite inadequate. Even more successful was the exhibition held in 1850 "of works of Ancient and Mediæval Art." The success of this exhibition was due to a large extent to the exertions made by Mr. (afterwards Sir) Augustus Wollaston Franks, the eminent archæologist, who in later years was the head of the British Museum Department of British and Mediæval Antiquities, etc. He acted as honorary secretary to the exhibition, and took infinite pains to ensure its success. This attracted even more public attention than the exhibitions of manufactures. Collectors, who had not then the numerous applications for loans to which they are now subjected, were liberal, and generously lent many objects of interest and value. The newspapers at the time were full of accounts of the exhibition and its contents.

As before said, these exhibitions led up to the international one of 1851; but the Society went on holding exhibitions on its own account. In 1848 an exhibition of recent inventions was held. This was composed partly of objects belonging to the Society's own collection, which

* Sir H. Cole's lecture had to be postponed, and was delivered in December, 1852.

Hosted by Google

had not then been finally disposed of, and inventions recently patented or registered under the Designs Act of 1851. This exhibition was a fairly good one. It contained 446 exhibits in all, of a rather miscellaneous character, some however of permanent interest and value. It remained open from December 26th, 1848, to January 30th, 1849. It was the first of an annual series continued regularly up to 1861. By that time its character had depreciated, and Sir Thomas Phillips, in the address which he delivered as Chairman of the Council in November, 1862, remarked that "the series have not kept pace with the progress of science, and have not been worthy of the present position of the Society." It was determined, in consequence of the 1862 Exhibition, not to hold an exhibition of inventions that year, and the opportunity was taken of letting the series come to an end.

Besides these exhibitions of an industrial character, the Society organised several exhibitions of pictures. As mentioned in a previous part of this article, the first action taken by Henry Cole in connection with the Society was the submission of a proposition for the holding of exhibitions of pictures by modern artists, in the hope that they would be a source of profit, from which funds might be provided for the establishment of a National Gallery of British Art. The proposal was that the profits from the exhibition of each artist's works should be expended in purchasing one or more of his pictures, and that these should be lent to the National Gallery, until enough had been collected to fill a special gallery. The idea was an admirable one. But the means proposed were quite inadequate, and, in spite of the enthusiasm which Henry Cole devoted to the scheme, it proved financially an absolute failure. The proposed series was started with an exhibition in 1848 of Mulready's works, the original idea of beginning with a collection of Landseer's not having for some reason been carried out. The financial result of the Mulready Exhibition was a small surplus, which was later on expended in the purchase of two of the artist's studies, and these were presented to the National Gallery. In 1849 an exhibition of Etty's works was arranged. But this resulted in a loss, and the idea of making money for the proposed gallery was abandoned. In fact, the Society was a heavy loser, for the expenses were ultimately paid only by the diversion, with the donor's consent, of a gift of £500 from Mrs. Acton, the widow of a member, which had been intended for the general purposes of the Society.* Some years later, in 1855, an exhibition of the works of the two brothers John and Alfred Chalon (both R.A.'s) was held, but it does not appear that this had any connection with Cole's scheme.† After the death of Sir William Ross, an exhibition of his miniatures was held in the Society's rooms in 1860, which attracted a good deal of interest, but did not produce any profit. Ross, as may be seen by reference to the list of the Society's prize-winners,‡ took many of the Society's prizes as a youth. He was long a member of the Society, was Chairman of the Committee of Fine Arts, and a member of the first Council.

It may be sufficient to mention that an exhibition of lithography was held in 1847, one of bookbinding in the same year, and a second of lithography in 1853. The photographic exhibition of 1852 will be referred to later, and the educational exhibition of 1854 has already been mentioned. In the year 1852 the idea was started of holding an exhibition of the products of India. The East India Company was approached, and promised assistance, and some steps were taken for organising such an exhibition in London. Eventually, however, there were difficulties in finding a suitable locality, and the collection was sent to the Dublin Exhibition of 1853, of which it formed an important section.

Since the first exhibition held by the Society in 1761 of agricultural and other machines for which the Society had offered prizes, it had always kept up a permanent collection of mechanical and other models. As these accumulated from time to time, their disposal was always a matter of difficulty, and every now and again we find notices of the older models, for which it was difficult to find room, being sold, or given away, or destroyed. Many of these one may legitimately regret. It would have been satisfactory if the original model of Sturgeon's electro-magnet had been preserved, and we should certainly be glad to possess now the whole collection which was shown in 1761.

But it must be remembered that such things accumulate rapidly, and that they soon become

* Mrs. Acton gave this money in 1837 to found prizes in memory of her husband, Samuel Acton, an architect, the prizes to be generally for subjects connected with architectural design or construction. She herself became a member after her husband's death.

† It is stated that this exhibition did not attract much attention, the works of the Chalons never acquiring much popularity.

Hosted by Google

obsolete and uninteresting; while they have to be kept for a great many years before they acquire antiquarian interest—an interest, indeed, which only belongs to the few survivals out of the great mass. When the Society began to hold temporary exhibitions, the space occupied by the old models was required, and they were finally disposed of in various ways. The bulk of them were presented in 1850 to Bennet Woodcroft, who was then Professor of Machinery at University College, London, the trustees of the College having undertaken to repair and preserve them.* Some of these eventually found their way into the Patent Office Museum† at South Kensington, which grew into the collection of engineering models now forming part of the Science Museum. Others were given to the South Kensington Museum at its foundation in 1857, and no doubt a great deal of what was really rubbish was quietly disposed of. The valuable collections of woods presented by Dr. Wallick in 1831 and by Captain Baker in 1834‡ were given to Kew in 1851.

Reference has already been made to the injurious effects on the Society's Premium List of the exclusion of patented articles from its awards, and the alteration in the regulations by which in 1845 patented articles were made eligible for such awards has also been mentioned. Not very long after this date, the Society, taking a different view of the value of patents, turned its attention to the amendment of the patent law, and in 1849 the Council, at the instigation of Henry Cole, appointed a Committee on the Rights of Inventors. It cannot be said that Cole had any deep or accurate knowledge of patent law; but he had on this, as on most subjects which he took up, very clear and definite ideas, and he never hesitated as to their correctness. The committee, however, which was appointed by the Council, included many members who were quite competent to supply any deficiency in Cole's knowledge, and he provided the moving force, which eventually brought about the much-needed reform in the law of patents in this country.

About a year after the appointment of this committee, Charles Dickens published in *Household Words* his well-known "Poor Man's Tale of a Patent"*; this, by the public attention it attracted to a very dull and uninteresting branch of legislation, greatly aided in securing the required reform.

The committee published several reports—reports containing many suggestions of considerable practical value. The general tendency of the reports was rather in favour of the French system—simple registration, *sans garantie du gouvernement*—a principle which has commended itself to a great many authorities on Patent Law. As a matter of fact, this has always really been the English system, which, while professing to be a grant direct from the Crown of an important monopoly, is, as has often been said, nothing except a license to go to law, and a registration of the date on which the inventor might commence his action. The logical French mind naturally agreed to a simple statement of the facts as they were. But the Englishman preferred something which appeared a great deal more important, professing, as it did, to be a grant direct from the Crown, although the imposing document, with the Great Seal attached to it, actually gave no more right than would have been conferred by a simple entry in a ledger. On the other hand, it has to be remembered that an invalid patent, which could not be maintained for a moment in any court of law, is often extremely valuable as a scarecrow, warning off trespassers from a territory to which the professed owner has no legal right, and this, perhaps, is after all the reason why the pretentious but illogical British system has so long been maintained.

In America and in Germany the opposite ideal has prevailed, and the attempt is made to provide a patentee with a genuine monopoly, by certifying to the originality of his ideas. The system in America used, if all tales be true, to be modified by the friendly relations existing between the patent agents and the officials, though no doubt this is no longer the case; while the German carried out his ideas to the utmost, and reduced them *ad absurdum* by such cases as refusing Siemens a patent for his regenerative furnace on the ground that it was anticipated by a mediæval oven, in which bread was baked after the material by which the oven had been heated was removed.

Whatever may be the best of these two opposite systems and ideals of patent law, it

---

* *Transactions*, Vol. LVII. p. xvii.

† The contents of this museum were the property either of the Commissioners of Patents or of their clerk, Woodcroft. They were to have been placed in the principal museum building, but Woodcroft objected to the admission fee of sixpence on "Students' days." Cole insisted, and neither would give way. The result was that the models of inventions were crowded into an unsightly iron shed, which was always open free to the public. So the authorities had their way, and nobody suffered except the public.

may suffice to say here that the view of the Society's committee was not adopted when the Bill, which in 1852 became an Act, for the reform of the Patent Law, was introduced into the House of Commons; but many of the other provisions were, and many parts of the Act were founded on the Society's suggestions. This Act, which came into force on October 1st, 1852, introduced many and great changes in the system for granting patents. It abolished the "hanapers" and "chaffwaxes," whom Dickens had held up to scorn; it simplified procedure, and reduced cost. It continued to be the law for many years, as it was not until 1883 that any important alterations were made, and in that later reform the Society, as may hereafter be recorded, had its due share. For the present, the work of the committee having been more or less satisfactorily accomplished, no further action was taken, and it was not reappointed after the passing of the Act.

The natural result of the new Act was an enormous increase in the number of patents applied for, and a consequent considerable revenue to the Patent Office. In the course of a few years the amount of patent fees had totalled up to a large sum, and suggestions began to be made that money provided by inventors ought to be applied in some way for their benefit, instead of being added to the public revenue. Sir Joseph Paxton, in 1856, addressed a letter to the Council on the subject, and the result was a committee, and a memorial to the Commissioners of Patents. Nothing, however, came of it, though the Commissioners seem to have been sympathetic enough, for they published year after year in their annual report a sort of mute appeal to the Treasury in the form of a statement of the accumulated surplus income they had earned. The last time this statement appeared was in 1881, in their report for the previous year. At that time the aggregate surplus income from October 1st, 1852, to the end of 1880 was £2,041,159 16*s.* 10*d.* The Treasury, however, were deaf to the appeal, and apparently saw no reason to abandon so convenient a source of revenue.

In December, 1852, an Exhibition of Photographs was arranged by the Society. This was the first public exhibition of photographs which had ever been held, though a few specimens had been exhibited in the Philosophical Instrument Section of the 1851 Exhibition. One hundred and twenty-nine pictures were shown, nearly all of them by the paper processes, though there were some collodion positives. At that time collodion had not been applied to the production of negatives, though a few months later (July, 1853) it was found that the picture on the collodion film on glass could be employed as a negative, and from that time forward it was so employed, to the ultimate exclusion of the earlier methods, in which paper rendered transparent by wax or other means had been used.

The formation of a Photographic Society was first proposed by Mr. Roger Fenton in April 1852, and in the same month Mr. Robert Hunt applied to the Society, asking for the use of the meeting-room for an inaugural meeting to establish such a society. The request was granted, but the meeting was not held until January, 1853. At this meeting Le Neve Foster, who had previously obtained the sanction of the Council to his suggestion, brought forward a proposal that instead of forming an independent society, a special section of the Society of Arts should be established dealing with photography. This proposal, however, did not meet with the approval of the photographers present, who were strongly in favour of an independent organisation, and the Photographic Society of Great Britain was established on January 20th, 1853. Sir Charles Eastlake, then President of the Royal Academy, became the first president of the new society. This, the earliest of all photographic societies, became the parent of many other similar bodies in this country, and its example was also soon followed in other countries.

The question of copyright in works of Art was taken up in March, 1858, when a committee was appointed by the Council to inquire into this subject. Of this committee Sir Charles Eastlake, then President of the Royal Academy, was appointed chairman, and he held the post until the termination of its work four years later. At that time there was almost no copyright in works of Art. The only Act in which any protection at all was given them was that known as Hogarth's Act (8 George II. c. 15), passed in 1735. It was connected with the name of Hogarth because it was obtained by him, mainly at his own expense, in order to protect his engravings, from the piracy of which he suffered considerable loss. There had been several amending Acts, but none which gave the author of an original work of Art the power of preventing its being reproduced and copies being sold.

The committee drafted a Bill to establish copyright in works of Fine Art, and this was introduced in the Session of 1860. In spite, however, of all the pressure that the Society

Hosted by Google

could bring to bear, by deputations to the Government, petitions, and otherwise, the Bill was not passed until July, 1862, and then only in an emasculated form, because the promoters were obliged to abandon its more important provisions in order to get the Act passed at all. Nevertheless, it was a very important reform, and it continued for many years to be the law on the subject. It established the existence of a copyright in works of Art, though, owing to the way in which one of the clauses was drafted, it made it rather uncertain as to whom the copyright should belong to in cases in which the artist had executed the work for a valuable consideration, or also if he had disposed of the work itself without either retaining or transferring the copyright. In spite, however, of its admitted imperfections, it worked fairly satisfactorily, and though it has been adversely criticised, it was at the time a great and valuable advantage to artists.

Its main provisions have been preserved in the most recent legislation on the subject, the Copyright Act (1 and 2 Geo. V. c. 46) passed in the Session of 1911, and in force since July 1st of the present year.

In 1859 the Society, at the suggestion of Wentworth Dilke, who was then the Chairman of Council, took up the question of musical pitch. The French standard pitch, then and since known as the Diapason Normal, became legal in France on July 1st, 1859; and it was no doubt the fact that the French had adopted a musical standard that led to the endeavour in this country to follow their example. The proposal that an attempt should be made to standardise musical pitch in this country was referred to a meeting of musicians, and after this a committee was appointed, which produced a very comprehensive and valuable report drawn up by Dr. Hullah.*

On the recommendations of the committee, a standard was suggested of 528 vibrations for the middle C of the pianoforte. The French Diapason Normal was 435 for the corresponding note A, and the Society's note A would then be 440; but instead of this, A was made 444 vibrations on the equal temperament system.

It is certainly unfortunate that the Society's committee did not adopt the just A 440, which would have been near enough to the French pitch for the two to have been treated as practically identical, and the probable result would have been that the French pitch would have been adopted in this country, and we should have got a uniform musical pitch many years ago. The question was further complicated by the fact that Mr. Griesbach, a musician who had concerned himself with experimental acoustics, and who had been entrusted by the Society with the tuning of the standard forks, unfortunately was incorrect in his determinations. His C fork was 534·5, instead of 528, and his A fork 445·7, instead of 444.*

The Society's well-intentioned and well-directed efforts had no practical result, and the suggested pitch was never to any extent adopted here or elsewhere. Much later on its existence became one of the obstacles to the adoption in this country of a standard pitch, and in 1886 it was referred to a committee to consider whether it was still desirable for the Society to maintain its theoretical C 528. On the advice of this committee, the Council in February, 1886, formally abandoned the Society of Arts pitch, and published their reason for so doing.†

The committee further advised that the Society in abandoning its own pitch should use its influence in furthering the adoption of the French pitch, from which, as before said, the Society's pitch, when accurately measured, did not really differ very much.

One of the schemes taken up by the Council aroused a great deal of ridicule, although it provided for what has now got to be considered as one of the necessaries of civilisation—that is, the supply of public water-closets and lavatories. Such conveniences had been arranged for in the 1851 Exhibition, and the charges made for their use resulted in a small profit.‡ It was thought, very properly, that similar conveniences ought to be provided in all great cities, and Sir Samuel Morton Peto, the well-known contractor, offered to defray the cost of the experiment, if the Society of Arts would undertake to provide waiting-rooms with suitable accommodation in London. Arrangements were made for two such places—one for gentlemen in Fleet Street, and one for ladies in Bedford Street, Strand.

The experiment turned out a complete failure, as the cost of establishment and current expenses for a period of about six months amounted to £492 17*s.* 4*d.*, whereas the total

* The report was printed in the *Journal* for June 8th, 1860, Vol. VIII. p. 572.

* These particulars are taken from a most interesting paper by Mr. A. J. Hipkins, read before the Society, in February, 1896, and published in the *Journal*, Vol. XLV. p. 535.

† *Journal* for February 12th, 1886, Vol. XXXVI. p. 265.

‡ The receipts were £2,470 and the expenses about £680. *Transactions*, Vol. LVII. p. xvii.

Hosted by Google

receipts were only £15 13*s.* 11*d.* Mr. Peto (as he then was) paid up the balance of £477 3*s.* 5*d.*, and the experiment was brought to an end. It, however, served its purpose in drawing attention to the necessity for such places. Later on the matter was taken up by the City Corporation, mainly owing to the recommendations of William Haywood, the City engineer (1846–1894), who originated the system of underground lavatories; and now London, which fifty or sixty years ago was probably the worst supplied of any capital in Europe with sanitary conveniences, is certainly the best.

Although the Society had long since given up the practice of making the bestowal of premiums its chief object, it never wholly abandoned that practice. Reference has been made more than once to the special prizes which were given during the years which preceded the 1851 Exhibition, and, indeed, gave the first stimulus to the idea of such an exhibition. The award of these special prizes was carried on from 1846 to 1850, and during that period the following well-known firms, amongst others, received the Society's medals:—Minton & Co. and Copeland (pottery); Osler & Co. and Pellatt & Co. (glass); Woollams & Co. and W. B. Simpson (paperhangings); the Coalbrookdale Co. (iron castings); Hunt and Roskill (jewellery); Crossley (carpets); Chubb (safes); and Leighton (bookbinding). Mention should also be made of the gold medal awarded to W. C. Siemens in 1850 for his regenerative condenser. This was an early and not very successful application of the regenerative principle. It was included in the patent for a regenerative engine (1847), and was the subject of a later patent (1849). The regenerative furnace was patented by Frederick Siemens in 1856.* Many years afterwards, when he occupied the post of Chairman of Council, Sir William Siemens said that this prize, the first he ever received, had been of the greatest encouragement to him. In the same year Henry Bessemer also had a gold medal for one of his minor inventions—a sugar-cane press. His improvements in steel manufacture were, of course, of a later date, his first patent connected with the "Bessemer process" having been taken out in 1855.

Inasmuch as the Society never formally discontinued its practice of awarding medals for meritorious inventions, it was always open to anybody to submit anything which he considered worthy of award, and from time to time new inventions of various sorts were so submitted, referred to a small committee or some individual expert, and received prizes. The publication of a premium list was also continued, and from time to time such a list was issued. It was of a very miscellaneous character, and produced but small results. The last list of this sort appeared in the *Journal* in 1873, but no awards, or very few, were made upon it.

During the period with which we are now engaged some special prizes of importance were offered. The Society's colour-box has already been mentioned.* This was the most popular of all its awards. The most important was the one offered for a microscope. In the summer of 1854 Dr. W. B. Carpenter suggested to the Council that a prize should be offered for a cheap microscope, the cost of such instruments being then such as to put them out of the reach of students and teachers of elementary science. The proposal was approved, and on the recommendation of a committee of microscopists, two medals were offered, one for a simple and one for a compound microscope, to be supplied at the price of 10*s.* 6*d.* and £3 3*s.* respectively. It was said that at such prices nothing of any practical use could be provided, but Messrs. Field, of Birmingham, produced two excellent instruments at the stipulated price, and the prizes were awarded to them. In the simple microscope, a tubular stem, which screwed into the top of the box containing the instrument when not in use, carried an inner rod fitted with a rack and pinion, and on this rod the lenses were mounted. There were three lenses, giving separately or in combination a range of magnification from above five to forty diameters. The top of the stem carried a stage, to which could be fitted a condensing lens for illumination or a stage-forceps. The little instrument, which was sold for 10*s.* 6*d.*, was well suited for the examination of botanical and other natural history specimens. In construction and design it seems to have been quite novel at the time.

The compound microscope was a really excellent instrument. It had a cast-iron stand, very firm and steady, two eye-pieces, two objectives giving a range from 25 to 200 diameters, a stage with rotating diaphragm, coarse and fine adjustments, adjustable mirror with plane and concave sides, separate condenser, stage-forceps and live-box. It was not, of course, an instrument suited for scientific research, but it was

* "Life of Sir William Siemens," by William Pole (1888), p. 75 *et seq.*

* *Journal*, June 21st, 1912, p. 764.

Hosted by Google

a thoroughly serviceable one, and nothing like it had ever before been produced at such a price. Dr. Carpenter, in his well-known book on the microscope, speaks highly of it, and in his third edition, published in 1872, he says that by the end of the year 1861, 1,800 instruments had been sold.

The principal value of the award was that it proved that a serviceable microscope could be produced at a cost far lower than that of any previous instrument, and the natural result followed that it had many successors, some of them improvements on the original, though perhaps there were none which competed with it in price. Certainly more than twenty years after its introduction microscopes were being sold which professed to be the Society of Arts pattern, and resembled it more or less closely both in character and merits. Later still, of course, much greater improvements were made, especially in the optical part, and inexpensive microscopes can now be bought compared with which the original Society's microscope is but a very inefficient tool. But it remains the first of its sort, and its introduction was a great boon to the scientific student of fifty years ago.

In 1857 Mr. John MacGregor offered the sum of £10 for a prize for a cheap writing-case suitable for the use of soldiers and sailors. The donor was well known as "Rob Roy" MacGregor, from his having invented what he called the "Rob Roy" canoe. This was a canoe rather larger than the double-paddle canoes which were then coming into fashion, covered in fore and aft, and capable of standing heavier weather than the ordinary canoe. MacGregor made various voyages in his favourite craft, including one down the Jordan (1868), which he described in a book that attracted a good deal of attention at the time. MacGregor's offer being considered insufficient, it was supplemented by a donation of an equal amount from the Rev. F. Trench, and the full prize of £20 was awarded in 1859 to Messrs. Parkins and Gotto for a writing-case which was sold at the price of 1*s.* 6*d.* It achieved a considerable amount of popularity, for 20,000 of them were sold; but its chief use was, like that of the colour-box and microscope, that it was succeeded by various forms of cheap desks and writing-cases, which were improvements on the original, and were sold at an almost equally moderate cost.

In addition to these there were several prizes for essays. In 1853 a prize of £50 was awarded to James Hole, of Leeds (Honorary Secretary to the Yorkshire Union of Mechanics' Institutions), for an essay on Mechanics' Institutes. To this reference has already been made.

In 1855 a prize of twenty-five guineas, offered by Benjamin Oliveira, M.P., was awarded to Charles Wye Williams for an essay on "The Prevention of the Smoke Nuisance," and two years later, in 1857, a prize of £200, which had been offered by Henry Johnson for an essay "on the present financial position of the country," was awarded to Edward Capps.

It should be added that in 1850 Scott Russell made a suggestion that medals should be given to the readers of the best papers every year. The suggestion was adopted and at once acted upon. The practice has been continued from that date down to the present time.

As the first award of the Swiney Prize was made in 1849, this would seem to be the proper place to insert some account of this curious bequest.

At the meeting held on February 7th, 1844, Arthur Aikin reported that during his secretaryship thirteen years before, which would mean some time in 1831, "a stranger called at this office and put into my hand the will of Dr. Swiney, sealed up in an enclosure, and immediately left." Dr. Aikin endeavoured to find out the doctor's address, but without success. When he retired from the secretaryship (1839) he took legal advice as to what had better be done with the packet, and was advised to open it, when he found a note from Dr. Swiney addressed to himself, expressing a wish that he should take charge of the will. This note was dated from Sidmouth Street, Gray's Inn Road, but no trace of Dr. Swiney could then be found, though inquiries were at once made.

Aikin handed over the will to William Tooke, the Society's honorary solicitor, and it remained in his hands until January, 1844, when Aikin was summoned to attend at Dr. Swiney's lodgings in Grove Street (now Arlington Road), Camden Town, where he had died on January 21st.

On the will being read, it appeared that the deceased had bequeathed, amongst other legacies, £5,000 Three per Cent. Consols to the Society of Arts, and a like amount to the British Museum, on the condition, so far as the Society of Arts was concerned, that a sum of £100 contained in a silver cup of the same value should be awarded on every fifth anniversary of Dr. Swiney's death as a prize to the author of the best published book on Jurisprudence.

Not a great deal has ever been found out about

Hosted by Google

Dr. George Swiney. He was said to be a son of Admiral Swiney, and a relation of Sir Humphry Davy. He was about fifty when he died, and had resided in Grove Street for about fifteen years. He was an M.D. of Edinburgh, where he graduated in 1816. He was certainly an eccentric character, and it was thought that some of his relations—for he appears to have had some — would have disputed the will. Nothing of the sort was done, and in due course the Society received its bequest. His eccentricity was displayed in the provisions made in his will for his funeral. These were all duly carried out. His coffin was covered with a yellow velvet pall, and followed by three girls in gay dresses. So curious a procession naturally attracted a great deal of attention, and the crowd was so great that there was some difficulty in carrying out the funeral. He was buried in the burial ground in Pratt Street, Camden Town. His tombstone having fallen into disrepair, it was twice repaired at the cost of the Society, the second time in 1899, when the old stone was in so bad a condition that it was thought best to renew it entirely and re-cut the inscription, which runs as follows:

HIC JACET
GEORGIUS SWINAEUS, MED. DOCT.
ANGLUS, SCOTUS, ET HIBERNICUS.
VIXIT SIMPLICITER
LUBENS OBIIT
12 KAL. FEB. MDCCCXLIV.
ANNO AETATIS SUAE L.*

Although the bequest was made to the Society of Arts alone, the adjudicators were, by the terms of the will, to be the members of the Society and the members of the Royal College of Physicians, "with the wives of such of them as happen to be married." It may be supposed that it was his connection with medicine which led him to drag in the College of Physicians; but it is only another proof of the man's eccentricity that on deciding to found an award connected with Jurisprudence he should select as adjudicators the members of two institutions neither of which has any connection with the law, or their members any special qualifications for the task. It, therefore, became desirable to consult with the College of Physicians as to the disposition of the prize, and before the time for the first award came round, the Council communicated with the College, with the result that an arrangement was arrived at that the award should be given alternately for General and Medical Jurisprudence. This arrangement has been amicably adhered to up to the present date.

When the question of designing a cup arose, Daniel Maclise was invited to submit a design, which was approved and accepted by the Council in May, 1849, the execution of the design being entrusted to Messrs. Garrard, the silversmiths. On two occasions since—in 1856 and 1894—the question has arisen of substituting a new design for that of Maclise, and the Council on both occasions went so far as to offer prizes for such a new design. In neither case, however, was the result satisfactory, and the cup is now, with some trifling alterations, the same as that originally designed by Maclise.

Besides the various matters already mentioned to which the special attention of the Society and its Council was directed, there were many other topics of which little more than bare mention must suffice.

In 1854 a Committee on Industrial Pathology was appointed, of which the most important members were Dr. T. K. Chambers and Mr. (afterwards Sir John) Simon. This Committee produced two reports.* Dr. Chambers also read a paper on the subject in June, 1854. In this paper,† and in the first report of the committee, the subject was dealt with in a general manner. The second report had special reference to trades which affected the eyes. Nothing very much seems to have come of the committee's efforts, and, indeed, this important subject hardly met with adequate treatment at the Society's hands.

The question of cheap international postage was taken up as early as 1851, and in 1852 the Council sent a deputation to Lord Granville, then Foreign Secretary, on the subject. In 1855 a parcel post was proposed for the first time. A committee reported on the proposal, and there was much discussion upon it, which bore fruit eventually, but not for many years.

The effects of the Paper Duty came under consideration from time to time, first in 1853, when the Council undertook an elaborate investigation into the effect of the duties, and collected the opinions of those whose interests were affected by them, including paper-makers, stationers, publishers, newspaper proprietors and editors, authors and traders using paper for manufacturing and other purposes A considerable amount of information collected from

* A few further details will be found in two articles in the *Journal*, Vol. XLVII. p. 660, and Vol. LVII. p. 440.

† *Ibid.*, Vol. II. p. 401.

Hosted by Google

these various classes was published. In 1860 a petition against what was called "taxes on knowledge" was addressed to the House of Commons. The duties were abolished in 1861, after a dispute between the two Houses of Parliament.

It is curious to note that when a proposal for national holidays was brought up before the Council in 1861, a resolution of disapproval was passed.

The centenary of the Society occurred in 1854, and was duly celebrated by a dinner at the Crystal Palace, at which Earl Granville presided. The Society's annual dinner was continued regularly up to 1862, when Mr. Gladstone was in the chair. This dinner was held in one of the refreshment rooms of the 1862 Exhibition building. Two years previously Mr. Disraeli presided. Other chairmen had been the Duke of Argyll, Lord Ashburton, Lord Stanley, the Earl of Carlisle, Lord Napier, and the Earl of Elgin. The numbers attending the dinner had gradually fallen off (there were 750 in 1854), and after 1862 it was not continued.

It is worth mentioning as a matter of record that the present Common Seal of the Society dates from 1856. It was adopted by a resolution of Council passed on June 18th in that year, and the old seal, with the design by Cipriani, which had been adopted in 1848, was given up.

When the Council met for the first time in December, 1845, the Society was not far from being bankrupt. All the available stock had been sold, and only a few trust funds, amounting to just £1,000, were left. The receipts for the year were insufficient to meet the annual expenditure; there was just £117 in the bank, and the Society was about £1,000 or so in debt. The accounts are not very clear, but that seems to have been about the actual state of the finances. It was obvious that if the Society was to go on at all, money had to be provided. Various plans were considered. Among other expedients suggested was the raising of a loan fund amongst the members. Various liberal offers were made to contribute to such a fund without requiring any interest, and several hundred pounds were thus paid, or promised, by some of the members. These contributions kept things going for a year or two, and then the Council received an offer from one of the members, Mr. Henry Hobhouse, to lend the Society a sum of £1,000 at $4\frac{1}{2}$ per cent. interest, to be secured by a debenture on the Society's property. This offer was gratefully accepted in May, 1848. It enabled temporary difficulties to be tided over, and in a year or so from this time the Society became practically solvent, the receipts from the increasing number of members and other sources being just about enough to balance the expenses. Still, when Mr. Hobhouse died in 1854 and his executors required the debenture to be taken up, the Council were not yet in a position to discharge the liability, but Mr. Thomas Twining, who was then a member of the Council, advanced £1,000 in the following year to pay Mr. Hobhouse's estate. This amount he was repaid in three instalments, the last in December, 1857.

The 1851 Exhibition and the growing reputation of the Society caused a large influx of members, and a similar result accrued from the Exhibition of 1862, so that the balance-sheet for the year ending June, 1862, showed a total of actual revenue of nearly £9,000, and a balance of income over expenditure of more than £1,000. The moneys in hand, and the amounts actually due and recoverable, were much more than sufficient to balance the actual liabilities.

That the actual financial condition of the Society was not generally appreciated, or its independence of official support generally known, is shown by an order made by the House of Lords in 1856 for a return of the sums of money granted by Government to the Society during the five years ending April of that year. The officials of the House, unable to supply the information themselves, applied for help to the Society, whereupon the Council directed the Secretary to reply that the Society had existed for over 100 years, and had never received any public money whatever, and that, therefore, the amount in question was "nil." There does not appear to have been any further correspondence. If the question were repeated at the present date, the same answer would serve.

When all the arrangements for the 1862 Exhibition had been successfully completed and the Society, then in the full tide of prosperity and success, was looking forward to the realisation of a considerable financial endowment from the anticipated profits of the Exhibition, their hopes were suddenly destroyed by the sudden and unexpected death of their President. The Prince Consort died in December, 1861. Though it was decided that the Exhibition should still be held, it was held during a period of national mourning, and without any of the pomp and circumstance which are essential to the success of such an undertaking. The result was a financial failure, which was only saved from disaster by the liberality of the contractors, who

Hosted by Google

took upon themselves the main burden of the loss.

But the loss of prospective revenue was not the greatest of the Society's deprivations. For eighteen years Prince Albert had been the active and watchful President of the Society. He had taken office when its fortunes were at their lowest ebb, its members few and falling away, its resources exhausted. If he had not consented to accept the Presidency, a very few more years would have seen its extinction. When he died it was flourishing and rich, the number of its supporters was just as many thousands as it had been hundreds, and it had accomplished an amount of public work of which any institution might have been proud. To attribute all this to the Prince Consort alone would be the merest sycophancy; but it is absolutely certain that but for his influence and his inspiring interest the work would never have been done. At his last appearance at the Society, when, in May, 1861, he presided at one of its meetings, he expressed his regret that of late he had been unable to give to its work the attention and the care he had given in earlier years. The Society of Arts was one of the first public institutions in the country to which he lent his patronage and his help. It repaid his attention by being amongst the first public bodies in England to appreciate him at his true value. For years he was unappreciated, misunderstood, unpopular; but by the members of the Society with whom he worked in pursuance of aims and objects on which his heart was set, he was from the first appreciated, understood and esteemed. It is something to the credit of the band of workers who used the organisation of the Society for the promotion of much public good, that they estimated at its true value the character of a man who for long was too apt to be depreciated by his adopted countrymen, and whose genuine worth was only fully known in the closing years of his life among them.

When the question of a national memorial to the Prince came under consideration, the Council at once voted what was — considering the Society's resources—the very large sum of £1,000 towards it, and also took steps to collect subscriptions among the individual members. Yet to many outside the Council this seemed insufficient, and a proposal was put forward for a separate special memorial of the Society's own. This was at first opposed by the Council, who were aware of the Queen's desire that the monument to her late husband should be the result of a single united national effort. The feeling, however, was too powerful. An influentially-signed memorial was presented to the Council calling on them to summon a second general meeting—one had already been held to endorse the action of the Council in contributing from the Society's funds to the national memorial—and the Council, submitting to the evident wishes of the members, at once abandoned all opposition and took the lead in the proposed movement. The result was that a fund was subscribed by the members, out of which were provided the two portraits of the Queen and of the Prince now in the meeting-room, and the bust of the Prince now in the ante-room.

A still finer memorial of the Prince is the Albert Medal founded in 1863, "for distinguished merit in promoting Arts, Manufactures, and Commerce," and awarded for the first time in 1864. This was established by the Council in pursuance of a suggestion made at the general meeting above mentioned, and is, of course, provided at the cost of the Society.

It has been awarded annually since it was first founded. Next year will complete a half-century of awards. The list of its recipients forms a complete record of the greatest of those who during that period have laboured to apply the advances of science to the practical benefit of mankind. Their names are fitly associated with that of the earnest philosopher and philanthropist, to commemorate whose association with the Society the medal was established, and while the renown of the recipients adds a constantly increasing value to the honour of the award, the services recognised by the medal may fitly be held to lend some further lustre to the reputation of the sagacious and benevolent Prince in whose memory it was founded.

SCOTTISH AGRICULTURAL CHANGES.*

As a sphere of agricultural production, Scotland offers a territory of 19,000,000 acres, of which fully 14 per cent. lies over the 1,500 feet limit, and nearly one-half is made up of rough hill-grazings rising in part over that level. This leaves for permanent cultivated pasture for rotation grasses and clovers, and for the surface over which the plough can annually range, not quite 5,000,000 acres. The "cultivated area" can be shown to have lost and gained in the interval if the statistics of the Highland and Agricultural Society in 1854–56 be taken as the starting point.

* Abstract of paper read before the Agricultural Section of the British Association, by Major P. G. Craigie, C.B.

Hosted by Google

Adding their estimate of 238,000 acres of arable land on the minor farms, 42,000 in number, to their more detailed analysis of the surface farmed by 43,000 larger occupiers, we find 3,750,000 acres was regarded as "arable." The advent of the Agricultural Returns of 1866 suggest as the feature of the intervening decade a large and rapid shrinkage of the arable acreage. Taking a five-year average up to 1870—only 3,360,000 acres could be so regarded. This figure rose to 3,670,000 acres in 1886–90 and did not fall below 3,500,000 acres till the twentieth century opened. It was 3,460,000 acres in 1901–05 and just under 3,400,000 in 1906–10, and therefore at the date of the new census of production. The changes between 1854–56 and 1866–70 included a diminution of 386,000 acres coincident with the abandonment of a large area of wheat after the abnormally high prices of the Crimean War disappeared. The latter changes, which we can measure more exactly from 1870 to 1910, show that some 200,000 acres of grain were lost, including 74,000 acres of wheat; there were nearly 100,000 acres of turnips and potatoes less, balanced by a growth of nearly 200,000 acres of rotation grasses. The permanent but cultivated grass in the same forty years augmented steadily from a round million to 1,500,000 acres. If crop areas are less the yields are all higher, and the wheat crop of the census year reached forty-one bushels per acre against less than twenty-eight in the fifties, barley thirty-six against thirty-three, and oats thirty-nine against thirty-two, while the potato yield of under four tons reached seven tons in 1908.

Concurrently the cattle maintained in 1854–56 exceeded 1,000,000 head. They rose to 1,157,000 in 1884–86, exceeded 1,200,000 head for 1890 to 1906, stood at 1,174,000 in 1908, and are again at 1,200,000 now. The sheep of 1854–56 only numbered 5,900,000. By 1884–86 they reached 6,848,000, attained a maximum of 7,623,000 in 1891, and with only two drops below the seven-million level were 7,439,000 in 1898, and are still 7,164,000. Herein the Scottish flocks maintained a record over all those of Western Europe, where the loss of sheep was large and significant. The pig stock of Scotland has always found a very small factor, but the level of 1908 at 144,000 was well above the total of the fifties, and is to-day over 170,000.

In the light of the new census the saleable output of Scottish agriculture, however, only reaches £23,150,000 per annum, the crops so far as sold accounting for over a fourth of £6,400,000, the animals and animal products £16,250,000, with £500,000 from "fruit, flowers, and timber," of which the fruit is about two-thirds. What these figures teach is a problem worthy of this new Section's attentive study. If the timber sales, calculated at £181,000 on 868,000 acres, and reaching thus only 4*s*. 2*d*. per acre, be deducted, the remaining agricultural area of under 14,000,000 acres would appear to return less than 31*s*. per acre, while the census report suggests that the rough grazing, of which Scotland shows 9,080,000 acres in its utilised area, can be reckoned to yield only 10*s*. to 12*s*. an acre of saleable output, if indeed this figure is not too high.

These features have to be reckoned with in any survey of the remaining scope for agricultural development, and give point to the directions in which the prospects are most hopeful. The prominent share which the livestock of the farm contributes to the total is enforced, and the student will find in the details now available as to the relative production of differing areas, the prevailing distribution of the land in farm units of various magnitude, and the economic or non-economic expenditure of labour force, topics which bear very closely indeed on the scope for scientific discovery.

FERRO-CONCRETE LINING TO MINE SHAFTS.

What is stated to be an entirely new application of ferro-concrete construction has recently been carried out at the Plenmeller Collieries, Haltwhistle, Northumberland, by Mr. T. Blandford, the engineer to the colliery company, who has adopted the system for lining two new shafts, instead of the usual brick lining, segmental slabs of concrete reinforced with expanded steel being used.

These slabs, which were cast in moulds on the site, were made of a size (3 ft. 1 in. by 1 ft. 6 ins.) convenient for handling, and, after being allowed to season, were lowered into the shaft and fixed in position. The lining of the shaft with such slabs was completed to a depth of 12 fathoms some time ago, and it has since been used under ordinary working conditions.

It is reported as having proved economical in construction and satisfactory in use; so that further lining of a similar nature is now in progress.

The slabs are 5 ins. in thickness, and are reinforced near their concave face with expanded steel, which has a cross-sectional area of ·25 of a square inch per foot of width short-way of mesh. The slabs are tongued and grooved on edges to allow of their fitting and keying into each other, the joints being filled with cement grout to make the segments a monolithic cylinder when placed in position. A hole was left in each slab—about 1 in. in diameter on the concave face, and slightly larger on the convex face—to allow of their being slung and lowered into position, as well as to serve as an inlet for cement grout to be injected into the concrete filling behind them after the slabs had been fixed in position.

The lining of the shafts was completed through water-bearing strata which had been previously treated by the François method of cementation, and the cavity between the reinforced concrete lining and the face of the strata, left in the process of sinking the shafts, was filled with ordinary concrete to a thickness of 9 ins. behind the lining

Hosted by Google

during the course of the fixing of the lining; this concrete being finally filled up solid by injection through the lining with cement grout, thus making it watertight.

It is said that the new lining possesses certain advantages over the ordinary brick lining, as being more watertight, and as not requiring any outlay in upkeep once the work is completed.

LAND BANKS.*

The feasibility of the establishment of land banks on a practical and an economic basis has been discussed intermittently for many years. The present depressed state of agriculture and the recent report of the Departmental Committee appointed by the Board of Agriculture and Fisheries to inquire into the position of tenant-farmers on the occasion of any change in the ownership of their holdings, directed attention to the question. Institutions formed for the sole purpose of financially assisting farmers in the purchase of their holdings and developing their industry have been established with marked success in other countries. Some solution of the present difficult question as to the future of agriculture in this country is surely possible. It may be that the prevalent feeling of unrest and uncertainty is accentuated by the campaign against land and its owners. On the one hand we find that owners of large estates are selling—in many cases at considerable loss—their properties, while on the other hand the farmers view with disfavour the idea of being tenants of either the Government or county councils.

It is submitted that a scheme could be devised which would enable farmers to purchase their holdings when offered for sale, without increasing the annual payments which they now make to their landlords in name of rent, and which would at the same return a reasonable rate of interest on the money advanced, provide a sinking fund for the redemption of the loan, and pay the working expenses of the institution.

The system of land banks proposed is self-supporting and free from State control. At first the institution would be confined in its operation to assisting farmers in the purchase of their holdings, with the ultimate intention of extending its scope, as the medium for the buying of seeds and manure, the purchase of pedigree stock, and the selling of farm produce.

The necessary capital to enable the bank to begin operations would be placed by the State at the disposal of the managers of the institution. Interest would be paid to the Government at 3 per cent. on the amount of capital advanced and outstanding from time to time. The Government get money from the Post Office Savings Bank depositors at $2\frac{1}{2}$ per cent. Further sums required would be obtained from the public by the issue of bonds, which bonds would be guaranteed, both as to principal and interest, by the State. There should be no difficulty in getting as much money as is required. At present when a depositor in a savings bank has at his credit the maximum limit, that money is, with his consent, used to purchase Consols, and the depositor thereafter has to take the risks of the market fluctuation of that stock. It is proposed to authorise the savings banks to issue transferable deposit receipts for multiples of £25 on behalf of the land banks, guaranteed by the State, repayable in ten, fifteen, or twenty years at a graduated rate of interest from $2\frac{3}{4}$ to $3\frac{1}{4}$ per cent.

Money would only be advanced to the tenant of a farm who had been on his holding for five years prior to the date of sale. The price would be fixed, failing agreement, by arbitration. The purchase money would be advanced at such a rate of interest as would enable the farmer to continue to pay annually a sum equal to the amount of his rent. The payment so to be received would include the interest paid by the bank for the money advanced, a sum towards a sinking fund, and a percentage to meet expenses and cover losses.

The bank would hold the property in security until the debt was paid. Any profit made would go to form a reserve fund. No dividends would be paid.

* Abstract of paper read before the Economic Science Section of the British Association, by Allan McNeil.

ARTS AND CRAFTS.

The Embroidery Exhibition at the Musée Galliera.—The collection of modern French embroidery of various kinds, which has occupied the Musée Galliera at Paris ever since June, is one of the most interesting summer exhibitions ever held at that gallery. To the English student it is, on account of its extreme comprehensiveness, perhaps of even more interest than to the French worker. English embroidery of late has been running rather on one line, and it would be difficult in this country, at the present moment, to get together a representative show of embroidery embracing so many different types of work as this French exhibition. The large exhibit sent by the Écoles Professionelles de la Ville de Paris was peculiarly interesting in this respect, for it showed what a thoroughly all-round training is being given in these schools. The work sent for exhibition was not above the level to which good schoolwork may reasonably be expected to attain; moreover, some of the naturalistic flower panels were of a type which we should consider old-fashioned and far from desirable. Still, the student who had learnt to do that kind of work, and had been given, in addition, a chance of adapting simple Breton embroidery to the needs of modern Parisian dress, and grasping the use of appliqué in the decoration of portières and the like, as these students seem to do, ought to be in a position to make a far better and more useful trade worker

Hosted by Google

than the girl who has only been taught to do one kind of work, however superior artistically that particular kind may be. The elaborate passementerie shown by the Paris schools was very well done indeed. That the French embroidery teaching is not all up to the level of that of the capital is shown by the not altogether successful appliqué exhibited by the Cours Municipal de Broderie Artistique de Lyon.

The church work is, as a whole, the least satisfactory section of the exhibition. The workmanship is hard and mechanical in the extreme, and the one effort in a new direction, a chasuble with a sprigged ground, decorated with orphreys, illustrating the life of St. Francis, is so weirdly up-to-date that one can hardly expect it to influence the trade work.

Amongst the embroidery, which is excellent of its kind without showing any remarkably new characteristics, may be mentioned the wonderful cutwork curtain of M. Edouard Privé, representing a group of mediæval minstrels, the white broderie des Vosges of M. Maurice Weil, and the delicate handkerchiefs of M. Gabriel Prévôt. There are embroidered trimmings of all sorts, some more gorgeous than beautiful, others characterised by a very exquisite taste. Among them the little samplers of simple braiding patterns of M. Paul Mail may be noticed as peculiarly suggestive.

A certain amount of French embroidery in string has been shown from time to time at international exhibitions, but this has hardly prepared us for the large landscape panels—formal gardens and the like of Mme. Ory-Robin and Mdlle. Sabine Desvallières. They are executed on a background of linen, almost entirely in appliqué of coarse, coloured linen damask, outlined with stout string. The description of them is by no means attractive, but the work itself, though very coarse and rough when you look carefully into it, forms very tasteful and wonderfully delicately toned decoration. The large screen of conventional design, carried out entirely in string, is again very pleasing and effective. The square panel of Mme. Laplace, worked in string couched down in filoselles of different colours, is an interesting departure in work of this kind. The other string work is, of course, though very pretty and delicate in tone, distinctly on the cold side, but string oversewn with coloured silks lends itself to a totally different and, in a way, a rather more interesting colour-scheme.

Some of the most interesting pieces of coloured silk embroidery are more or less spoilt by their association with paint. M. René Lalique's fine portière, with its swirling-haired wind amongst the trees, is the most striking thing in the exhibition and a wonderful piece of colour. The salmonish pink of the ground, from which the head only slightly distinguishes itself, and the purply-blue trees form a most attractive bit of colouring; but the needle has been helped out of its difficulties by the brush, and the piece is far less satisfying than it would have been had it been entirely executed in needlework. Another rather amusing departure is squares of silk treated apparently in some way analogous to marbled end-papers, and then slightly embroidered in places. The effect is very fresh, but one wonders rather how it has been attained, and whether the real charm of the colour will remain, or whether it is merely temporary. In any case, though the embroidery in a way helps the effect, it takes quite a subsidiary place, and one feels that this kind of work is not really suitable to an embroidery exhibition.

Apart from these more ambitious exhibits, there is a mass of good, competent work of all kinds, ranging from the coarsest appliqué to the finest white work. The design, too, is as varied as the execution—naturalistic, conventional, geometric, grave or gay, according to the fancy of the designer and the needs of the work. It is really in this diversity, even more than in the real merit of the best individual works, that the strength of the exhibition lies.

French and English Furniture.—The two kinds of work which probably occur to most people when they think of French artistic manufactures are jewellery and furniture, and far apart as these two crafts are, there is one characteristic in which the French work in both departments is, for the most part, distinguished from the English—its sense of style. It is true that this sense manifests itself in very different ways, but it is there none the less. With regard to furniture, the French have so firm a hold on the styles of the later Louis and of the Empire that they seem unable to depart from them. It is quite astonishing to the Englishman, used to seeing a good deal of fairly simple furniture of a modern type, to note in the ordinary Paris shops how extraordinarily little there is which can be said to be on anything but strictly traditional lines. It seems almost as though invention had stopped a hundred years or so ago, and people had done nothing but copy ever since. That is, of course, an overstatement of the case, but the fact remains that the type has persisted, without that amount of modification which natural growth would suggest. This is, in a way, a pity. Any sort of stopping short is a thing to be regretted; but still it must be remembered that this does not imply in France just what it would in England. When English people, with much care and forethought, furnish their rooms consistently in the style of a by-gone time, the result may be quite charming to the eye, but it suggests at least a trifle of affectation: we are inclined to think that the room is not the spontaneous expression of the owner's own taste. The modern Chippendale is not what the workman naturally produces, it is a style he has more or less laboriously learnt. On the other side of the Channel it is rather different; people use, say, Empire furniture more or less naturally, not because it is the fashion to return to a past style, but because that style is still

Hosted by Google

alive for them; they take it as a matter of course, and the maker for his part has grown up making it. The result is that French furniture, whether we like it or no, and however much we may deplore its want of originality, has a certain quality—that of style—a style which really belongs to it and has not been assumed, which saves it from ever falling to the lowest depths.

French Jewellery.—Matters are rather different when we come to jewellery. In this craft the French artist craftsman is as unfettered as the Englishman, and he often does work which at first sight has nothing to do with traditional styles, but his output is characterised by a sense of style none the less, and by a distinction which English artistic jewellery often lacks. The British craft jeweller is at present a comparatively new departure, and far from having the traditions of his trade at his fingers' ends, he has often had to learn them late in life—has sometimes deliberately turned his back on them. The result is that, though he has achieved a very considerable measure of success he has done it for the most part by limiting himself to simple workmanship. It remains to be seen whether he will content himself permanently with this or will go further. The Frenchman, on the other hand, betrays his accomplishment at every turn. He revels in his material and loves to show his mastery over it. When he errs he does so not as a rule on the side of simplicity but on that of the over-elaboration which comes of the desire to produce a *tour-de-force.* Surely the ideal jewellery would be characterised by a combination of these two qualities, the English simplicity and the French mastery of the material. The *tour-de-force* is often enough ugly, but this is not because it is accomplished, but because it is lacking in restraint. That is a point which should be realised rather more than it is.

With regard to the French work of the moment, it is interesting to note that a fair amount of work in the Egyptian style seems still to be done, and that a great deal of attention is being paid to the production of signet and other rings with large stones. The setting and mounting of such stones is providing scope for a good deal of ingenuity which is by no means misplaced. This appears to be a field in which our own craft workers have so far done very little and which might provide an opening.

OBITUARY.

SIR HORATIO DAVID DAVIES, K.C.M.G.—Sir Horatio Davies died at his residence, Watcombe Hall, Torquay, on the 18th inst., at the age of seventy. After being educated at Dulwich College, he entered the well-known catering business of Pimm's in the Poultry. In 1885 he became a member of the Court of Common Council for Cheap Ward; in 1887–8 he served in the office of Sheriff of London and Middlesex, and in 1889 he was elected to the Court of Aldermen for Bishopsgate Ward. From 1895 to 1906 he sat in the House of Commons as representative of Chatham. But he is, perhaps, best remembered as Lord Mayor of London, a post which he occupied in 1897–8, when he is said to have entertained more lavishly than any previous occupant of the Mansion House. At the close of his mayoralty he received the honour of K.C.M.G.

In addition to Pimm's Restaurant, Sir Horatio Davies was interested in the "Ship and Turtle" in Leadenhall Street. He was also the owner of hotel property at Eastbourne and in the Isle of Wight, and was engaged in building operations on a large estate at Nottingham and elsewhere. He had travelled much, and had only a few weeks ago returned from a journey to South Africa. He was a Justice of the Peace and Deputy Lieutenant for Kent, where he owned till recently the estate of Wateringbury Place, near Maidstone; a past Master of the Spectacle Makers' and Loriners' Companies, an Officer of the Legion of Honour, and a leading Freemason.

For many years he was an officer in the 3rd Middlesex Artillery Volunteers, and retired with the honorary rank of Lieutenant-Colonel and the Volunteer Decoration.

Sir Horatio Davies was the possessor of a valuable collection of pictures by old and modern masters, and of old silver and other curiosities. He became a member of the Royal Society of Arts in 1888.

GENERAL NOTES.

VICTORIA AND ALBERT MUSEUM.—The Department of Engraving, Illustration and Design, of the Victoria and Albert Museum, has recently acquired, by purchase, a large number of original studies by the late Frederick Shields, for his well-known illustrations to Bunyan's "Pilgrim's Progress." They have been mounted with the wood-engravings to which each group relates; and a selection of about ninety is now exhibited in Room 70. This series, with a set of drawings for Defoe's "Plague of London," some of which are now in the Manchester Art Gallery, constitute Shields' chief contribution to the great period of English book illustration, the "sixties"; and, when published, they received high praise from Rossetti and other artists, as well as from John Ruskin. The same room also contains two original pen-drawings by the late E. A. Abbey, R.A., for "She Stoops to Conquer" (1885), and "The Quiet Life" (1889), given to the museum by Mrs. Abbey, in memory of the artist, as well as another study purchased for the collection, which is thus enriched with a representation of the work of one of the most distinguished of the pioneers of modern methods of illustration. Mr. Stanhope Forbes, R.A., has given eleven etchings by the late Mrs. Stanhope

Hosted by Google

Forbes, whose graceful and accomplished work in this medium, belonging to the earlier period of her artistic career, is by no means as widely known as it deserves. Among other recent accessions, wholly or in part now exhibited, are four drawings by the late L. R. Garrido (1868–1909), given by Mrs. Garrido; a collection of twenty-one working proofs, etc., of etchings by the late David Law (1831–1902) given by Miss Law; two etchings by Mr. D. Y. Cameron, A.R.A., "Rameses II." and "The Lion and the Unicorn," given anonymously; and four studies by James Ward, R.A., given by Mr. A. E. Anderson; four studies for "The Harvest Moon," and other pictures, by G. H. Mason, A.R.A., have been purchased, and are also shown.

Basket-making in Jamaica.—Although baskets made in Jamaica are on sale and in general use throughout the island, their manufacture is confined chiefly to the parish of St. Elizabeth in the south-western part of Jamaica. At Lacovia, in that parish, the principal manufacturer makes such a variety of baskets that it takes sixty-seven samples to show all the styles. The material mostly used is the leaf of the palmetto, which is locally known as the "bull thatch palm." This tree thrives well in the morasses. The leaves of the palm are cut off and placed in the sun for three days; then split into the desired widths and exposed to the sun for six days more, after which the strips are bleached in the dew for a night, and again exposed to the sun for a day, when the material is ready for use. The baskets are all made by hand. A favourite style is called "bankra," a covered basket made in many sizes. Bamboo is used for making strong market baskets. Although an immense number of baskets are manufactured and sold in Jamaica, the market being especially brisk during the tourist season, the quantity exported is insignificant. Considering the attractiveness and cheapness of many of these baskets, it seems that it would be possible to build up a considerable export trade for them.

Algerian Vegetable Fibre.—Vegetable fibre, or *crin végétal*, is made from the leaves of a dwarf palm which clings to the soil tenaciously. Its presence was a serious obstacle to the pioneers of Algerian colonisation, and it had to be fought foot by foot. It was not then known that the plant would become a source of wealth to the colony, and that it would be more and more sought after as a commercial product. The palm grows abundantly in Algeria in sandy soil, among rocky mountains, as well as in rich, deep soil. Heat, cold, rain and drought do not harm it. After several attempts had been made to utilise the palm, satisfactory results were obtained in 1847. The leaves were separated by a comb into long and flexible filaments, which were twisted into rope shape. The palm leaves are plucked by the Arabs only when they have nothing else to do, the work being poorly paid. In years of drought it is their only resource. Treated on the spot, simply and economicaly, and slightly dried, the leaves are sold by local manufacturers to export firms on the sea coast, where, after a fews days' exposure to the sun, they are made up into bales. *Crin végétal* serves well for stuffing furniture and mattresses, and it can be used for cleaning and polishing floors, wood, and brass work. Its use for domestic and other purposes is causing increased sale, replacing many other more expensive articles. The most important customers for Algerian *crin végétal* are the United States, Italy, Germany, Austria, Belgium, and France.

Exposure Tests of Light Aluminium Alloys.—In a paper read before the Mechanical Science Section of the British Association, Professor Ernest Wilson remarks that during the past eleven years reports on this subject have been presented to the Association at fairly regular intervals. The tests show that alloying commercial aluminium with copper, unaccompanied by iron, nickel, or manganese, is not satisfactory. A 2·6 per cent. copper alloy has completely deteriorated in ten years, and increased its electrical resistance 25 per cent. "Duralumin" is a copper manganese alloy of aluminium, with the addition of about 0·5 per cent. magnesium. During the last year a specimen has increased its electrical resistance 5·15 per cent. It would be interesting to know if this is due to the comparatively large percentage of copper (3·5 to 5·5) which this alloy is stated to contain, or if the percentage of manganese (0·5 to 0·8) is too low. This alloy has attracted attention in that a breaking-load as high as 90,000 pounds can be obtained, if desired, according to treatment. Its specific electrical resistance at 15° C. is about twice that of commercial aluminium. A specimen of high-conductivity copper wire has increased its electrical resistance 1·2 per cent. in one year.

Monograph on Italian Irrigation.—The executive committee of the International Exhibition of Irrigation and Rice Culture, which will be held this autumn at Vercelli, have offered prizes for a monograph on irrigation in Italy at the present time. The first, of 1,000 lire (£40) and a gold medal, and the second, of 500 lire (£20), will be awarded to the writers of the two best. They must contain descriptions of all the principal works of irrigation in the country (Italy), and the results obtained since they have been opened; tables showing the lengths and principal dimensions of the chief canals, where situated, quantity of water supplied, the areas irrigated, results obtained, etc.; description of the various systems employed for the measurement and distribution of water in the various regions in Italy; consumption of water for the different kinds of crop; legislation in Italy for the use and distribution of water for agricultural purposes; as well as other data relating to irrigation in that country.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICE.

CANTOR LECTURES.

The Cantor Lectures on "The Materials and Methods of Decorative Painting," by Mr. Noel Heaton, B.Sc., F.C.S., have been reprinted from the *Journal*, and the pamphlet (price one shilling) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, W.C.

A full list of the Cantor Lectures, which have been published separately, and are still on sale, can also be obtained on application.

PROCEEDINGS OF THE SOCIETY.

HOWARD LECTURES.

HEAVY OIL ENGINES.

By CAPT. H. RIALL SANKEY, R.E. (Retired), M.Inst.C.E.

Lecture I.—Delivered April 29th, 1912.

INTRODUCTION.

The name "oil engine" includes to-day many types and varieties. About twenty years ago there was only one type on the market, represented by such engines as the Priestman and the Hornsby-Ackroyd. These engines used paraffin or ordinary lamp oil, having a specific gravity of about 0·82. This oil requires heat for vaporisation in order to produce an explosive mixture, and engines using it are now included in the category of "heavy oil" engines.

Later, in the year 1890, Daimler brought out his petrol engine, in which a volatile oil of 0·680 sp. gr. was used. With such oils vaporisation takes place at ordinary temperatures and air is readily "carburetted," thus forming an explosive mixture. Such engines are called "light oil" engines.

Comparatively recently the Diesel oil engine was placed on the market, and in this type of engine the oil is not vaporised to form an explosive mixture, but is mechanically pulverised, and burns in the engine cylinder, that is, it does not explode in the ordinary sense of the word. The Diesel engine is also a "heavy oil" engine.

There are numerous varieties of each type of engine, sometimes called after the kind of oil they use, such as benzine engines, petrol engines, paraffin engines, and crude oil engines. Incidentally, the latter is a misnomer, because the crude oil is that which comes out of the ground, and contains all the other oils. These engines can therefore be distinguished as follows:—

Light Oil Engines.—An explosive mixture is formed by carburation at atmospheric temperatures. The oils used have a specific gravity as low as 0·68, but usually about 0·72. They are called "Petrol engines."

Heavy Oil Engines.—An explosive mixture is formed by vaporisation at comparatively high temperature—or a combustible mixture as formed by mechanical pulverisation—specific gravity of oils, 0·8 to 1·0.

These lectures will be confined to heavy oil engines, and will deal principally with the Diesel engine, as being the most important.

Heavy oil engines can also be classed as:—

(*a*) Explosion engines;

(*b*) Combustion engines.

Three types of the former are illustrated in Figs. 1, 2 and 3.* Fig. 1 represents the type of the original Priestman engine, in which the oil is vaporised in a hot bulb. Before starting, this bulb has to be heated by means of a lamp, which takes about a quarter of an hour. In Fig. 2 the oil is vaporised by falling on to

* These figures, as well as Figures 13, 16, 21 and 22, are reproduced by permission of the American Society of Mechanical Engineers, from a paper by H. R. Setz on "Oil Engines."

Hosted by Google

baffle plates, which are heated by the exhaust, and forms an explosive mixture with the air drawn in on the suction stroke. Such engines are ignited by means of an electric spark, and have to be started by means of petrol, and the heavy oil can be introduced so soon as the baffle plates have reached a sufficient temperature. In Fig. 3 there is a stream of air compressed from 8 lbs. to 25 lbs. per square inch, which pulverises the oil, after which it is immediately vaporised in the chamber heated by the exhaust gases.

The second class, namely, combustion engines, consists of the Diesel engine and of the so-called semi-Diesel engine. In the former, pure air is compressed in the cylinder to a pressure (450 lbs. to 500 lbs. per square inch) sufficient to cause ignition, and the oil is pulverised and introduced into the cylinder at the top of stroke by means of air at a still higher pressure (700 lbs. to 900 lbs. per square inch).

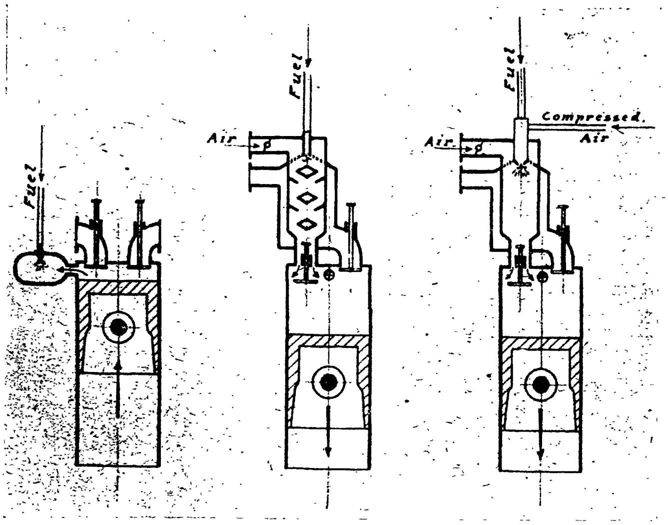

FIG. 1. FIG. 2. FIG. 3.

In the semi-Diesel engine, pure air is also compressed in the cylinder, but only to about 200 or 250 lbs. per square inch, the ignition temperature being reached by means of a hot bulb into which the oil is injected by a pump at the top of the stroke.

Judged by the sizes, and the total horse-power at work or under construction, the Diesel engine is to-day the most important type, and will, therefore, be first considered.

Short History of Diesel Engine.

Not many years ago the Diesel engine was known as a promising oil engine to few engineers, but its development has been so rapid—not to say extraordinary—that assuredly everyone, not only engineers, has some acquaintance with it. The reason is obvious, namely, that it can utilise and convert into power types of oil hitherto unusable for power, and it works reliably and with the greatest economy of fuel. This result has, however, only been obtained by long, costly, and patient research and trial.

A short historical account of the developments will, therefore, be of interest, and the following has kindly been supplied by the Maschinenfabrik Augsburg-Nürnberg Co., who were the pioneers in the experimental work.

Historical Sketch of the Diesel Oil Engine.

Dr. Diesel applied for his patents in Germany and other countries in 1892.

The Augsburg works of the Maschinenfabrik Augsburg-Nürnberg Co., in conjunction with Messrs. Krupp, of Essen, entered into an agreement with Dr. Diesel to make all tests and experiments for the carrying out of the patents and to install at Augsburg a special laboratory, equipped with all the necessary technical and scientific means for this purpose. The two German patents were acquired at the same time (1893) by the two above-mentioned firms.

Dr. Diesel was at the head of the laboratory, but all the costs were borne by the Maschinen-fabrik Augsburg-Nürnberg Co., and Messrs. Krupp. The engine illustrated in Fig. 4 was the first experimental engine.

It was soon found that the chief idea of Dr. Diesel—viz., to obtain the highest temperature

Hosted by Google

of the cycle before the actual combustion, and to get an isothermic combustion—could not be realised, and that water-jacketting of the cylinder, which Dr. Diesel thought he could avoid, was necessary.

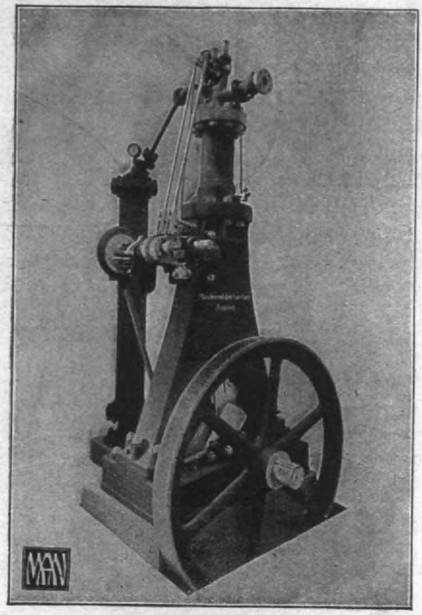

FIG. 4.

Notwithstanding these initial disappointments, the owner of the Augsburg works—Herr von Buz (now Geheimer Kommerzienrat Heinrich von Buz)—and the Augsburg engineers, especially Herr Lauster, persevered and succeeded in building, in 1897, the first engine of 20 B.H.P. (Fig. 5), which was tested by many scientific authorities, and placed the Diesel engine at once, so far as thermal efficiency was concerned, at the head of all prime movers.

This was the first task, the carrying out of which was only rendered possible by sacrifices on the part of the Augsburg works of the Maschinenfabrik Augsburg-Nürnberg Co. and Messrs. Krupp.

The second task, viz., to build a commercially useful engine, was then undertaken by the Maschinenfabrik Augsburg-Nürnberg Co. and their several licensees, as well as by firms in other countries, as, *e.g.*, Mirrlees & Watson, who had bought the patents of their respective countries from Dr. Diesel, after the first scientifically successful engine had been completed at Augsburg.

After the first experiments, however, firms like Sulzer Bros., Carel Frères, Gasmotorenfabrik Deutz, etc., gave the whole thing up, although they had partly received drawings and technical hints from the Augsburg works of the Maschinenfabrik Augsburg-Nürnberg Co.

Only the Augsburg works of the Maschinenfabrik Augsburg-Nürnberg Co. succeeded, and sold and delivered in the beginning of 1898 an engine of 60 B.H.P. (Fig. 6) to the match factory "Union," at Kempten, which is still in satisfactory working order.

The commercial success attained by the Augsburg works of the Maschinenfabrik Augsburg-Nürnberg Co., then induced other firms, such as Sulzer Bros., Carel Frères, Mirrlees, Bickerton & Day, and others, to begin again, in 1903–04 or later, the manufacture of Diesel engines.

The history of the English Diesel business is briefly as follows.

In March, 1897, Dr. Diesel sold his patents to Mirrlees, Watson & Yaryan Co., Ltd., and they built an experimental engine. Meanwhile, a special company, "Allgemeine Gesellschaft für Dieselmotoren A.G., Augsburg," had acquired, in September 1898, all the patent rights of Dr. Diesel. This company bought the patents

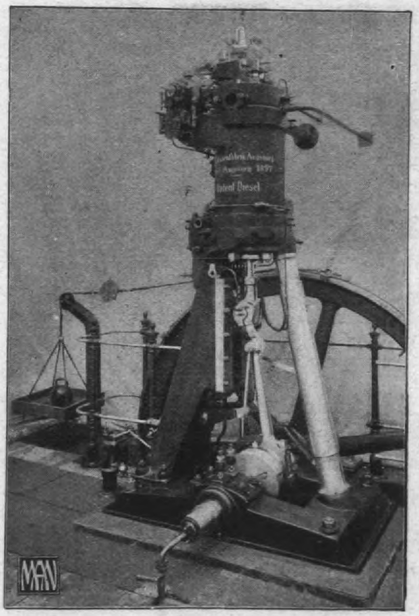

FIG. 5.

back from Mirrlees, Watson & Co., in September 1899, and entered into a new agreement with this firm in November 1899.

In November 1900, the "Allgemeine" sold the patent rights for England and the Colonies, and

Hosted by Google

some other countries, to the Diesel Engine Co., Limited.

The Diesel Engine Co. then became, and until recently was, exclusively a selling company, and during the first years only sold Diesel engines of the Augsburg works of the Maschinenfabrik Augsburg-Nürnberg Co.

The two chief English patents covering the Diesel cycle, and belonging to the Diesel Engine Co., expired in 1906 and 1909, so that the manufacture of Diesel engines can now be attempted by anybody in this country.

The Maschinenfabrik Augsburg-Nürnberg Co. were, therefore, the pioneers, and have since retained their place at the head of all manufacturers.

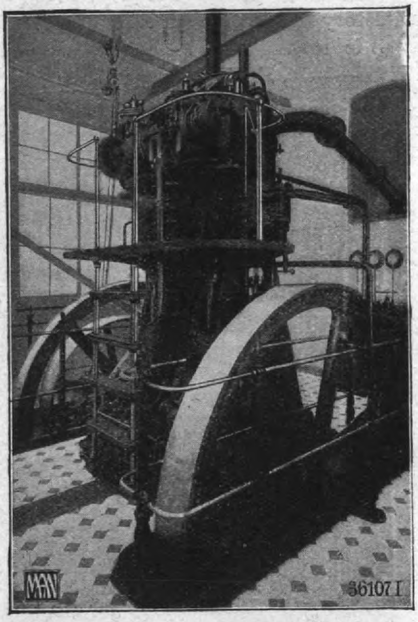

Fig. 6.

A great number of Diesel engines, of the vertical single-acting, four-cycle type, were built by the Maschinenfabrik Augsburg-Nürnberg Co. in the following years. When the first really large engines of 600 and 800 B.H.P. were built in 1906–07, it became apparent that they could be built better, simpler and more accessible on the lines of the then well-proved horizontal double-acting Nuremberg gas engines. An experimental tandem engine of 600 B.H.P. was built at Augsburg, which proved quite satisfactory, and was soon followed by an order for an engine of 1,600 to 2,000 B.H.P. from the Municipal Electricity Works of Halle (Germany). At present eighteen such horizontal double-acting engines, ranging from 600 to 2,000 B.H.P., are under construction. Fig. 7 illustrates such horizontal engines.

Somewhat later, the Maschinenfabrik Augsburg-Nürnberg Co., after exhaustive experiments, also placed on the market horizontal single-acting Diesel engines, of the four-cycle and two-cycle type for medium powers.

Since 1903 many firms have undertaken the manufacture of Diesel engines, and to-day the horse-power at work cannot be far short of one million.

The first reversing marine engine was built by Messrs. Sulzer in 1905 for a boat on the Lake of Geneva, and since then the marine Diesel engine has made rapid strides. Engines of 4,000 h.p. have been built for this purpose, and much larger are in contemplation.

Until recently, the development of the Diesel engine has been slow in this country, due, to a certain extent, to a want of enterprise and to distaste for anything new, especially if it has not originated in this country. The slow development, however, is in large measure due to cheap coal, although this country has an enormous field throughout the Empire, in many parts of which oil, when used in the Diesel engine, is a cheaper fuel than coal.

The recent papers by Mr. Milton, read before the Institution of Naval Architects, and by Dr. Diesel, read before the Institution of Mechanical Engineers, have, however, awakened interest, especially for marine work. A full historical account will be found in Dr. Diesel's paper; the above is only a sketch intended to show the rapid development of the engine.

Thermodynamical Considerations.

All prime movers by means of which useful work can be produced by utilising a "heat fall," can be divided into two main groups—namely, external-combustion engines and internal-combustion engines. The heavy oil engines belong to the latter.

In the case of water wheels and water turbines, a "water-fall" is utilised, and the maximum energy available per pound of water is proportional to the height through which the water falls. Practically, however, only a fraction, varying from, say, 50 to 80 per cent. of this maximum energy is converted into useful work.

In the case of a heat engine the "heat fall" is measured by the number of thermal units theoretically rendered available for utilisation as work by the change in condition produced in

Hosted by Google

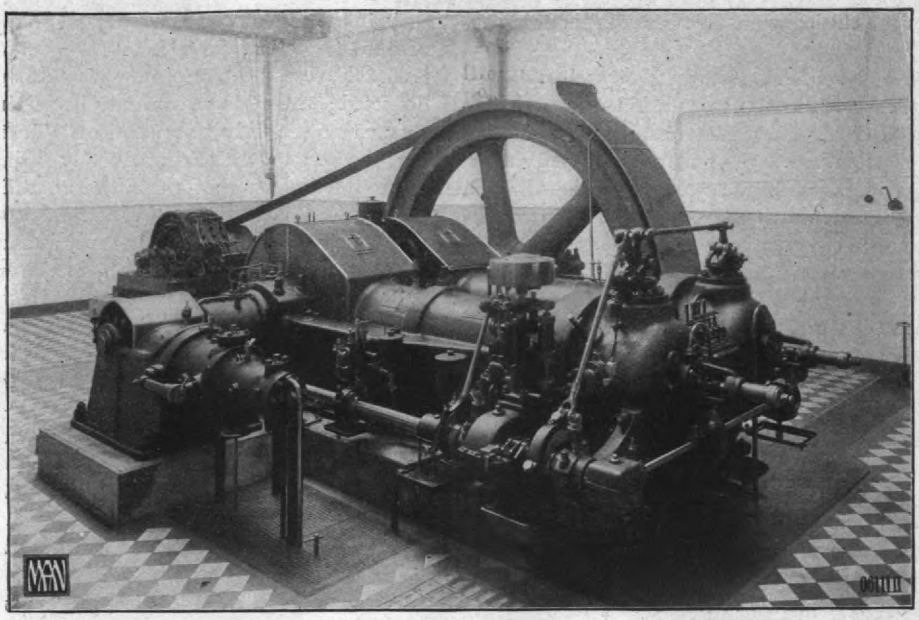

Fig. 7.

the working fluid by the agency of the cycle operations followed by the particular type of heat engine adopted. In passing through the engine the temperature of the fluid is reduced, but in no actual engine is this fall of temperature, by itself, a measure of the heat fall, because it also depends, and in large measure, on the manner in which the heat is introduced into the working fluid, and on the manner in which it is abstracted therefrom.

The simplest way of exhibiting the above is by means of a heat chart, the ordinates of which represent absolute temperature to an equally divided scale, the base line being at the temperature of absolute zero. Let the point P (Fig. 8) represent the location on the chart of the fluid before any heat is introduced, and let P_1 be its position after heat has been introduced. Further, let the chart be so constructed that the area $P\ P_1\ P_2\ P_3$ represents the number of heat units introduced in some manner or other, and let this amount be H. By virtue of the mechanism of the engine, the heat energy does work which is suitably transmitted to, say, a revolving shaft. Let P_2 represent the condition of the fluid at the beginning of the period of abstraction of heat, and let P_3 represent its condition at the end of this period, then the area $P\ P_3\ P_2\ P_1$ represents the heat abstracted, and clearly the difference between the heat introduced and that abstracted—namely, the heat introduced by the area $P\ P_1\ P_2\ P_3$ is the heat converted into work. Let this amount be represented by W, then the ratio $\frac{W}{H}$ is known as the thermal efficiency of the operation. The endeavour is to make this ratio as large as possible, but, unfortunately, for various reasons, it cannot be made very large.

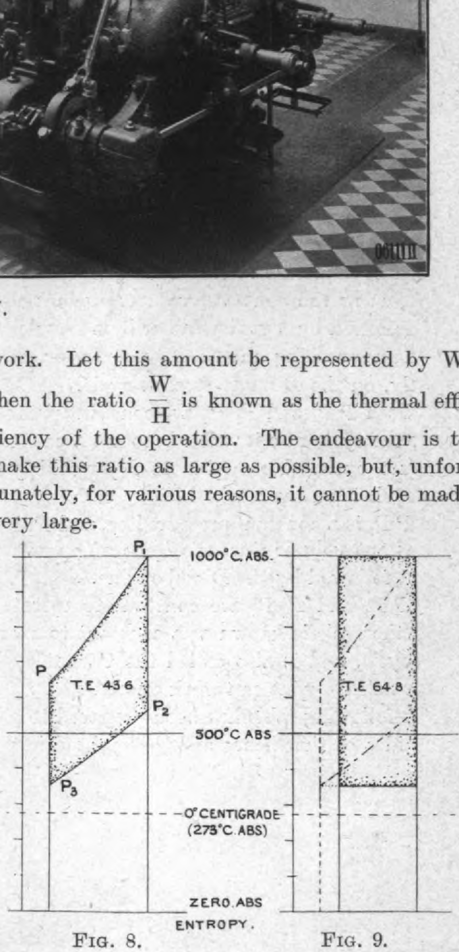

Fig. 8. Fig. 9.

In Fig. 9 a special case is illustrated, in which both $P\ P_1$ and $P_2\ P_3$ are horizontal—that is to say, the heat is introduced at constant temperature, T_1, and is also abstracted at constant temperature, T_3. This figure has been so drawn that the amount of heat introduced, H, is the same as in Fig. 8, and it is clear that the ratio $\frac{W_1}{H}$ is greater in this case than in the former, and it can in fact be proved to be the greatest

Hosted by Google

thermal efficiency possible between the temperatures T_1 and T_3.

It can further be shown that each point on this chart defines the condition of the fluid—that is to say, curved lines can be drawn on the chart from which the pressure and the volume at any point can be ascertained. Thus, if through the admission of heat from P to P_1 the volume remains constant, the line $P P_1$ forms part of a constant volume line; or, again, if the pressure were to remain constant, it would form part of a constant pressure line. These same remarks apply to line $P_2 P_3$ followed during the abstraction of heat usually known as the exhaust period.

If both $P P_1$ and $P_2 P_3$ are constant volume lines, the cycle of operation is known as a constant volume cycle, and it will be further observed that since $P P_2$ and $P_1 P_2$ are vertical lines, obviously, from the construction of the chart there will be no change of heat during those parts of the cycle. These lines are known as adiabatics. The cycle just described is known as the constant volume cycle, and is that followed by a gas engine or by an explosion oil engine working on the Otto cycle, or, more strictly, on the Beau-de-Rochas cycle.

If both $P P_1$ and $P_2 P_3$ are constant pressure lines, the cycle of operation becomes a constant pressure cycle. No engine to-day working on this cycle is on the market.

If $P P_1$ is a constant pressure line, and $P_2 P_3$ is a constant volume line, the cycle of operations is that followed by the Diesel engine.

If $P P_1$ and $P_2 P_3$ are constant temperature lines, the cycle is known as a constant temperature cycle, and is also called the Carnot cycle. No practical engine can work on this cycle.

The following table has been prepared to give some idea of the theoretical thermal efficiencies obtainable under various conditions—

As in the case of water engines, only a fraction of the theoretical possibilities are practically realisable, because various losses have to be deducted; these losses can only be minimised, they cannot entirely be got rid of. That is to say, the amount of heat practically utilised as work is less than that theoretically utilisable, and the ratio of the lesser amount to that supplied is called the actual thermal efficiency of the engine.

The ratio between the actual thermal efficiency of an engine and the theoretical thermal efficiency of its cycle is known as the "efficiency ratio," and substantially may be taken as follows, for certain typical heat engines:—Non-condensing steam engines using saturated steam, 60 to 80 per cent.; condensing steam engine, using superheated steam, 50 to 70 per cent.; gas engines, 80 to 88 per cent.; oil engines (explosion type) and Diesel engines, about 75 per cent.

The actual thermal efficiencies of various engines referred to in Table I. have been deduced from the above, and in the figures given under that heading allowance has also been made in the case of steam engines for boiler losses, etc., and for producer losses in the case of gas engines.

It has already been stated that between given values of the highest and lowest temperatures occurring in the cycle, the Carnot cycle has the greatest possible thermal efficiency, and, for the sake of comparison, this thermal efficiency has been added to the table for each item.

As a further comparison, heat chart diagrams of some of the engines entered in the table are given in Fig. 10 on the assumption that the amount of heat introduced is the same in all cases, and this being so, the areas enclosed in thick lines, representing the possible conversion into work, are in proportion to the theoretical

TABLE I.

Description of Plant.	Abs. temperatures. Theoretical °C.		Thermal Efficiency.			
	Highest.	Lowest.	Theoretical Cycle.	Carnot Cycle.	Actual Plant from per B.H.P.	Actual Plant to per B.H.P.
Non-Condensing Steam Plant . . .	458	373	17·8	18·2	4	8
Condensing Steam Plant Superheated	561	310	31·0	45·0	10	15
Gas Engine and Producer	2100	370	47·0	82·5	16	24
Oil Engine	2000	370	40·0	82·0	16	19
Diesel Engine	2000	370	56·0	82·0	26	32

Hosted by Google

thermal efficiencies. The various losses are deducted, and the remainder indicated by the areas shaded by dots are proportional to the actual thermal efficiencies.

The great thermal efficiency of the Carnot cycle has been a considerable temptation to inventors forgetful of the fact that, apart from other difficulties, such an engine would have a

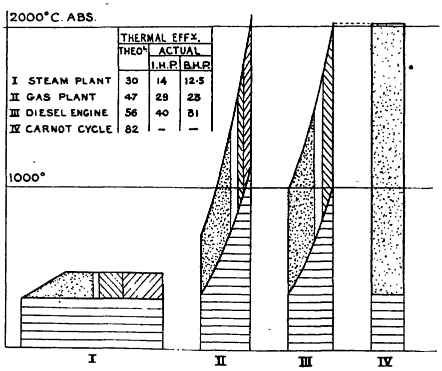

FIG. 10.

very small mean pressure in the cylinder, and therefore would require enormous pistons and cylinders.

However, it was from an attempt of this nature on the part of Dr. Diesel that he gradually evolved the oil engine which bears his name. In 1892 he published a book which was translated into English by Bryan Donkin, jun., entitled, "Theory and Construction of a Rational Heat Motor," in which he argues that if combustion is carried on in a cylinder at constant temperature, theoretically a slightly higher efficiency than that of the Carnot cycle can be obtained, because a less weight of the fluid has to be compressed than has to be expanded, owing to the addition of fuel being made after compression. He appears, however, to have forgotten that the abstraction of heat in the case he considered could not be effected at constant temperature, or at any rate he assumed that it could so be extracted. The cycle he then proposed was, therefore, unrealisable; moreover, it is not at present practically possible so to regulate the oil admission as to obtain a constant temperature, but rather an approximately constant pressure is obtained. Hence, as a practical matter, as already stated, the Diesel oil engine works on a constant-pressure volume cycle, the thermal efficiency of which is given in Fig. 10, whereas, under the same range of temperatures Herr Diesel expected to get a thermal efficiency of 0·855, corresponding to a coal consumption of 0·25 lb. per h.p., for it should be mentioned that the first trials were made with pulverised coal and not with oil, and designs for an engine working in this manner are given in the book referred to.

In the ordinary gas engine or explosion oil engine the heat is introduced to the working fluid theoretically at constant volume, because, the mixture being exploded, the combustion is complete before the piston moves from the dead point. Practically, however, a considerable portion is added at increasing volume, because the explosion is not instantaneous, and this is a cause of loss. In the Diesel engine the oil is introduced comparatively gradually, and at such a rate that the pressure remains nearly constant: the indicator diagram will, therefore, theoretically have a flat top; practically, only an approximation to a flat top is obtained, as shown in Fig. 11, which gives both a theoretical and a practical diagram. On this figure are also shown theoretical and practical indicator diagrams of an ordinary gas engine for the sake of comparison.

These indicator diagrams illustrate the fundamental difference between the Diesel and the Otto engines. In the Diesel engine the continued combustion of the oil is achieved, as already mentioned, by pulverising it and injecting it in this state into the cylinder by means of an air blast, and, owing to previous compression up to about thirty-two atmospheres (500 lbs. per square inch), the air in the cylinder is at a sufficiently high temperature to ignite the oil.

Attention is called to the difference in the compression reached, as shown in these two

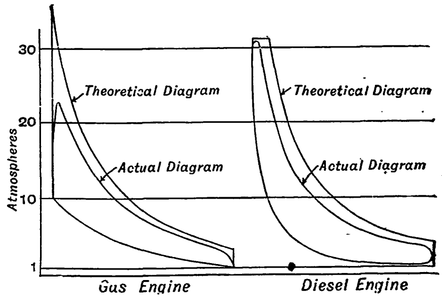

FIG. 11.

diagrams; in the case of the Otto engine, the explosive charge is compressed about 130 lbs. per square inch gauge; a greater pressure is not practically permissible for fear of pre-ignition. In fact, this is about the highest compression used in gas engines working with producer gas; with town gas it is less, and with ordinary oil or petrol engines the pressure has to be still

Hosted by Google

further reduced—namely, to about 80 lbs. per square inch, and it is this low compression which prevents this latter type of engine having a high thermal efficiency.

In the Diesel engine, however, the combustible matter is added at the top of the stroke on the turn of the piston; only air is compressed, and therefore pre-ignition, in the ordinary sense, is not to be feared; consequently, much higher compressions are possible, which is the real cause of the great thermal efficiency of the Diesel engine. This high compression raises the temperature of the air to about 700° C., so that the temperature in the cylinder at the moment the oil is injected is sufficient to cause its ignition, thus no special means of ignition, such as the electric spark or the hot tube required by the ordinary gas engine, are needed.

In the semi-Diesel engine, as already stated, the compression of pure air is considerably less, and the pulverised fuel is injected into a hot

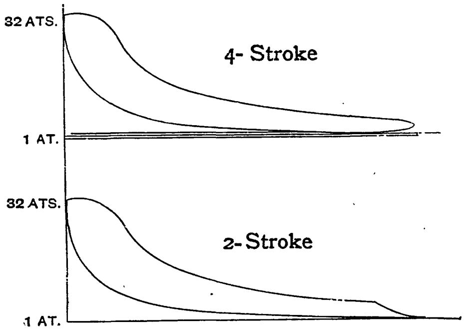

FIG. 12.

bulb, which causes it to ignite. The heat is introduced into the working substance partially at constant volume and partially at constant pressure.

This immunity from pre-ignition of the Diesel and semi-Diesel engines may be regarded as a great advantage these types have over the ordinary gas or oil engine, because it may be safely said that a large proportion of the troubles which have arisen in connection with large gas engines are due to pre-ignition.

The cycle followed by the Diesel engine can now be stated completely, and is illustrated diagrammatically in Figs. 11 and 13. A charge of pure air is sucked into the cylinder through the air valve, and on the return stroke this air is compressed to a pressure of from 450 lbs. to 500 lbs. per square inch, so that the ratio of compression needed is about thirteen to one (as against six to one for the ordinary gas engine), and the clearance in the cylinder is arranged accordingly. At from 1° to 2° before the end of the stroke the fuel valve opens and the charge of oil is pulverised by means of an air blast and a special device to be described in detail later, and is injected into the cylinder. The requisite amount of oil, determined by the action of the governor, is forced into a space above the fuel valve by means of a fuel pump. The pressure of the air blast varies from 750 lbs. to 900 lbs. per square inch, according to the proportion of the full load the engine is working at, and an air-compressor has to be provided for supplying this high-pressure air.

After combustion, expansion of the products of combustion takes place, until the exhaust valve opens, which occurs at about 0·9 of the stroke, and then the pressure in the cylinder suddenly drops to atmosphere. Finally, the piston, on its return stroke, sweeps out the remaining products of combustion, and the cycle is complete. It will be seen that four strokes, namely two up and two down (in a vertical engine), are needed for one complete cycle, and the engine described therefore works on a four-stroke cycle, corresponding in this respect to the Otto or Beau de Rochas cycle of a gas engine.

Up to the present the greater number of Diesel engines have been designed on the four-stroke cycle; arrangements can, however, be made to introduce a blast of air into the cylinder at the moment the exhaust valve opens, and thus, not only will the products of combustion be swept out, but also the cylinder will be filled with pure air. The cylinder is then in the same condition as on the second up-stroke of the four-cycle type—that is to say, pure air is compressed, and hence fuel can be injected at the end of this stroke. A combustion stroke will therefore take place at each down stroke, and the engine then works on a two-stroke cycle. In this way double the power can be obtained from a given cylinder. This type of Diesel engine is now being rapidly developed, and eventually will probably be the only type used for large marine engines.

Gas engines also work on the two-stroke, or Clarke cycle, the products of combustion being scavenged just before the explosive mixture is introduced into the cylinder. In this case the difficulty arises that if the scavenge is too powerful, unburned gas will be blown into the exhaust and lost, because it has to be admitted into the cylinder immediately after the scavenging air and before the exhaust ports are closed (except in the case of the Oechelhauser engine).

Hosted by Google

If, however, the scavenge is reduced, a portion of the exhaust will be left in the cylinder, thus reducing the weight of explosive charge. These difficulties do not occur with the Diesel engine, because the fuel is not admitted until later, and within reason any amount of air can be blown through the cylinder to clear out completely the products of combustion. Hence the Diesel engine is essentially adapted for a two-stroke engine.

The indicator diagram of the two-stroke engine is somewhat different from that of the four-stroke, and to illustrate this difference average indicator diagrams of a two-stroke and of a four-stroke engine are given in Fig. 12.

Dugald Clerk, in 1887, built an engine using coal gas which followed the Diesel cycle, and which he called a "flame" engine. The air was alone compressed in the cylinder, the gas being compressed separately by a side pump forced into the engine cylinder through a series of gas jets, and ignited exactly as it entered. This engine worked very well, but the mean pressures obtained were too low, because the compression pressure was too low; namely, only 90 lbs. per square inch.*

ESSENTIAL ELEMENTS OF A DIESEL ENGINE.

It will thus be seen that the Diesel engine can work either as a four-stroke or as a two-stroke engine. In the four-stroke engine the following are the essential elements, illustrated diagrammatically in Fig. 13 :—

1. A cylinder, in which works a piston connected in the usual way to a crank shaft. This cylinder, surrounded by a water jacket to keep it cool, is fitted with—*a*, an air valve; *b*, a fuel valve; *c*, an exhaust valve. All these valves are opened by a two-to-one shaft, driven by the engine, and generally closed by means of springs.

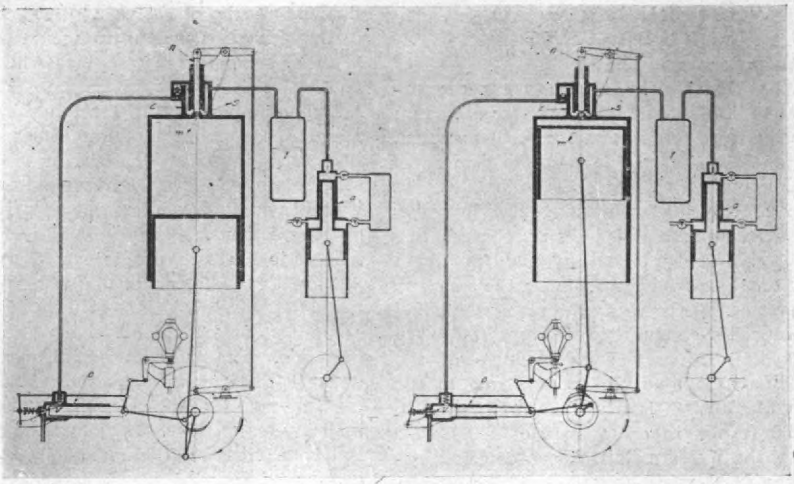

FIG. 13.

2. A fuel pump regulated by the governor.

3. An air-compressor to provide high-pressure air for pulverising and injecting the fuel.

In the case of the two-stroke Diesel engine, the essential elements are the same as those given above; the two-to-one shaft, however, runs at the same speed as the crank shaft of the engine, and a low-pressure air-compressor or blower has to be added for supplying the scavenging blast of air.

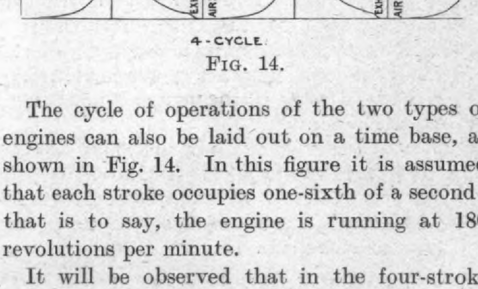

FIG. 14.

The cycle of operations of the two types of engines can also be laid out on a time base, as shown in Fig. 14. In this figure it is assumed that each stroke occupies one-sixth of a second; that is to say, the engine is running at 180 revolutions per minute.

It will be observed that in the four-stroke cycle the exhaust pressure is slightly above and

* See Cantor Lecture, "Internal Combustion Engines," by Dugald Clerk, M.Inst.C.E., p. 25.

Hosted by Google

the air-suction pressure slightly below atmosphere. In the two-stroke cycle there is very little time for the exhaust and scavenge, and obviously the turning effort is far better than in the four-stroke cycle.

THE NATIONALISATION OF THE WESTERN RAILROAD OF FRANCE.*

Was the purchase by the State of the West of France Railroad caused by a desire to reduce expenditure and to improve the means of transit? No; but following the elections of 1906, M. Clemenceau, then Prime Minister, felt a desire to give some satisfaction to the Socialist and Radical-Socialist parties by "socialising" something. In November he handed in a proposal for the purchase of the Western line. What was the argument put forth in favour of State ownership? That the company would never be able to repay the sums which had been advanced to guarantee the interest. On December 31st, 1905, the indebtedness of the Western line amounted, in moneys due to the State, to 302,569,000 francs, and in interest to 117,300,000 francs, in all a total of 419,880,000 francs; but the Western Railroad possessed rolling-stock estimated at 351 millions. Subjecting it to a reduction of 30 per cent., the price to be paid would therefore have been 245 million francs. That difference of 174 millions was the great argument put forward by the redemptionists to hasten the purchase.

How could redemption protect those interests? The guarantee of interest to shareholders amounted annually to 11,550,000 francs, and was to come to an end in 1935; it was prorogated till 1951, and afterwards until 1956, reduced to 6,300,000 francs. The remaining sums due by the company were written down as being 7,122,000 francs, and not 174 millions.

The results of the management by the State were increased expenditure: the deficiency of the Western Railroad was, in 1903, 28,522,000 francs; that of the State, in 1912, was 83,675,000 francs; the increase of working expenses amounts to 72,304,000 francs, out of which the staff draws 52,296,000 francs. According to M. Pierre Baudin's report to the Senate, on a total of 67,967 persons employed, 36,816, or 54 per cent., were told off on sick leave, and it was necessary to increase the workers by 7,440 units. While working expenses from 1908 to 1912 have increased by 72,304,000 francs, the gross receipts have risen from 217,645,000 to 244,335,000 francs, the increase only representing 26,689,000 francs.

As for the effect on State credit, the Minister of Finance issued this year 4 per cent. bonds. At once the 3 per cent. fell to 93·65, and afterwards to 91·95.

The redemption of the West of France Railroad was a complete failure.

* Abstract of a paper read by M. Yves Guyot before the Economic Section of the British Association.

CO-PARTNERSHIP IN INDUSTRY.*

Profit-sharing is still a very rare thing in the aggregate of all business. Full details of existing schemes in the United Kingdom will be contained in the forthcoming report by the Board of Trade. Profit-sharing is distinguished from gain-sharing by the fact that the latter is a premium on efficiency, payable irrespective of the general financial results of the year. But it is less easy to distinguish profit-sharing from co-partnership. Two types of schemes are examined which claim this distinctive title:—

I. The Co-partnership Trust in Lever Brothers, Limited, soap-makers, of Port Sunlight, Cheshire, instituted in 1909.—The main features of the scheme are as follows: Partnership certificates are issued to qualified workers who sign the co-partnership agreement. These certificates entitle the holders to share in profits over 5 per cent. *pari passu* with the holders of the ordinary shares, and the dividends, which are paid into savings-bank account to individual co-partners, are freely withdrawable. The certificates have no market value, and the scale of annual issue (at present 10 per cent. on salaries and wages) is determined by the majority shareholder. The allocation of certificates is left to trustees (the directors), assisted by an advisory committee of workers. On retirement, partnership certificates are exchanged on certain terms for preferential certificates limited to 5 per cent. interest, which lapse at death. Workers who voluntarily leave the business or break their co-partnership agreement forfeit all rights in the scrip. In considering the possibility of imitation, regard must be had to the following points: (1) That the firm is an exceptionally successful one; (2) that it is the maker of a proprietary article; (3) that it has previously conferred other benefits upon its employees. Figures for 1911: Certificates issued and outstanding—A, Partnership, £275,429; B, Preferential, £23,302 (nominal value); dividend on A, at 10 per cent., £27,543; on B, at 5 per cent., £1,165.

II. Co-partnership in the gas industry, with special reference to the South Metropolitan Company.—Co-partnership began here in 1889, but since 1907 there has been rapid expansion, so that there are now thirty-six companies practising profit-sharing or co-partnership: total capital, £50,000,000; total of employees affected, 22,000. The financial side of the South Metropolitan scheme is based on a sliding-scale. For every 1*d*. reduction in the price of gas shareholders get a further 2*s*. 8*d*. per cent. of dividend, and co-partners a bonus of ¾ per cent. Officers and workers are included in the scheme. The present bonus is 8½ per cent., and the stock held by employees over £300,000. The bonus, which is the absolute property of the co-partner, is not paid in cash but reserved, half for savings account, withdrawable in special circumstances, and half for investment in the company's

* Abstract of paper read before the Economic Science Section of the British Association by C. R. Fay, M.A.

Hosted by Google

stock. Similar provisions appear in the schemes of other gas companies, with minor modifications.

The advantages of the scheme are: (1) the addition to wages, (2) the promotion of thrift, (3) the creation of good feeling and a sense of co-ownership. Sir George Livesey (late chairman of the South Metropolitan) claimed that the scheme paid the masters no less than the men, and had its influence in reducing the cost of labour and the price of gas. It is difficult, however, to establish exactly this casual connection. The gas industry is peculiar, having a partial monopoly of supply and a steady demand. Also its stocks are, in general, not speculative.

In certain cases these schemes have been opposed by the trade unions. Co-partnership makes strikes improbable and (while the co-partnership agreement, current for three or six months, lasts) punishable under the Conspiracy and Property Act of 1875. But the agreements give security to the men also. The most powerful ties of co-partnership are to be found in the democratic machinery by which the scheme is worked. A co-partnership committee (composed of the chairman of the board of directors and twenty-six representatives of the board and twenty-seven representatives of the co-partners) manages the scheme and does other valuable work connected with accidents, superannuation, and insurance. Finally, the scheme safeguards the interests of consumers, who are peculiarly benefited when they are drawn from a working-class district.

Municipalities are liable to labour trouble, but co-partnership would be difficult to apply here, owing to the special nature of municipal finance. The Stafford Corporation (gas and electricity departments) practises gain-sharing only. Co-partnership, like syndicalism, emphasises the necessity of a closer connection between the worker and his work. But it is doubtful if special legislation, favouring co-partnership, would be of any value to the movement.

LIBERATION OF HYDROCYANIC ACID FROM LINSEED.*

A farmer considers linseed to be one of the safest cattle-foods, but the chemist has shown that linseed readily liberates hydrocyanic acid. The author has attempted to measure the rate of liberation of hydrocyanic acid from linseed under conditions somewhat similar to those occurring during digestion. The rate at which hydrocyanic acid is liberated from linseed depends upon many details, but among the many causes which retard the liberation of hydrocyanic acid, the degree of acidity is pre-eminent. So sensitive is the enzyme responsible for the liberation of hydrocyanic acid, that acidity only $\frac{1}{200}$ normal in strength is sufficient greatly to retard the liberation of hydrocyanic acid. Under no ordinary conditions can linseed liberate hydrocyanic acid in the acid juices of the stomach. When "mash" is used for feeding cattle, linseed is often left for a short time, sufficient to liberate much of the hydrocyanic acid contained in the glucoside of the linseed. In such circumstances "mash" might be dangerous, but the danger could be completely removed by making the "mash" slightly acid. Hay, straw, pulped roots, and many other ingredients of "mash" contain traces of acids which would generally be sufficient to check the rate of liberation of hydrocyanic acid. Hence, in practice, hydrocyanic acid is rarely liberated from linseed, either before or after eating.

* Abstract of paper read before the Agricultural Section the British Association by S. H. Collins.

ENGINEERING AND ÆSTHETICS.*

There are injuries which we may inflict upon the community other than those to health and physical comfort. Every one, even the least cultured, has some sense of the beautiful and the comely, and is affected by the aspects of his environment more than he himself can realise. The engineer, then, whose works needlessly offend even the most fastidious taste is acting contrary to the spirit of his profession, at its best. There has been far too great a disregard of æsthetic considerations in the everyday work of the engineer—we usually take a too exclusively utilitarian view of our calling. We should not be prepared to accept, as referring to the arts we practise at their best, the distinction drawn by a philosophical writer between "the *mechanical* arts which can be efficiently exercised by mere trained habit, rote, or calculation," and "the fine arts which have to be exercised by a higher order of powers." And I think it can be shown that a greater regard for artistic merit in our designs would not necessarily lead to extravagance, but, in many cases, would conduce to economy and efficiency. It is at least true—and much less than the whole truth—that greater artistic merit than is commonly found in our works could be attained with no sacrifice of structural fitness, or of suitability for the purposes they are designed to serve.

There was a time when engineers made desperate attempts to secure artistic effects by the embellishment of their productions with features which they believed to be ornamental. Fortunately the standard of taste has risen above and beyond this practice in the case of most members of our profession and most of our clients. We are all familiar with illustrations of philosophical instruments, and other mechanical contrivances of the early times, that vied in lavishness of adornment—though not in artistic merit—with those wonderful astronomical appliances hat were carried—as trophies of war!—from Pekin to Sans Souci. Many of us can remember a time when the practice had not altogether disappeared, even

* Extract from the Presidential Address to the Engineering Section of the British Association by Professor Archibald Barr, D.Sc.

Hosted by Google

in the design of steam engines, lathes, and other products of the mechanical engineer's workshop. I well remember in my apprenticeship days the building of a beam engine that was a triumph of ingenuity in the misapplication of decorative features. In place of the mildly ornamented pillars and entablature of Watt's design, there was provided, for the support of the journals of the beam, a pair of A frames constructed in the form of elaborately moulded Gothic arches flanked by lesser arches on each side, while the beam itself, and many other parts, were plentifully provided with even less appropriate embellishments borrowed from the art of the stonemason. It is some consolation to remember that the clients for whom the engine was built were not of this country, and that the design itself was not a product of the workshop that was favoured with the contract to produce this amazing piece of cast-iron architecture. We have all seen wrought-iron bridges the unattractive features of which were concealed by cast-iron masks—in the form of panelling, or of sham pillars and arches with no visible means of support—that not only have no connection with the structural scheme, but suggest types of construction that could not, by any possibility, meet the requirements.

THE FRENCH SILK-WEAVING INDUSTRY AND ITS FUTURE.

While at one time Lyons was the unchallenged centre for silk textiles, the production of the looms of that district now has to compete with the silk fabrics of other countries. Twenty years ago it was publicly stated in Lyons that it would not be surprising if the weaving of fine silk damask, brocaded velvet, or a piece of cloth of gold would become a historical curiosity, and to perpetuate their manufacture would be as costly for the State as the maintenance of the Gobelins establishment. Although twenty years have elapsed since this statement was uttered, the weavers of Lyons are still able to make on their hand-looms fabrics that in skilled workmanship, richness of design, and purity of quality, are unsurpassed.

In order that silk-weaving in its most perfect form as known in Lyons may not become a lost art, vigorous measures are being taken to preserve from extinction the weaving of the fine textiles for which the district is famous. Silk manufacturers and municipal authorities and legislators are facing the situation in all seriousness. A committee was appointed by the Chamber of Deputies to study the demands relative to the condition of silk manufacture at Lyons, and the best means to be taken for transforming the old looms.

This committee was divided into three sub-committees, one of which devoted itself entirely to the question of weaving in Lyons, and made its investigations last year. This sub-committee reported that it would urge the Government to pass a law to improve the present state of the silk industry of Lyons. It was asked that an annual subvention of £20,000 be granted during a period of twenty years, to be placed at the disposal of a particular bank of master silk weavers of Lyons. This sum should be applied immediately to engage apprentices with the master weavers for the manufacture of high-class figured textiles for upholstery and other purposes. The apprenticeship is to be organised and controlled by the special bank in question. About £800 should be paid out as bounties to master weavers and to apprentices. The apprenticeship will last three years, and every three months an apprentice will receive pecuniary assistance, more at the beginning and less at the end of his time, because during the third year he will be in a position to earn something. According to the American Consul at Lyons the total amount allowed to each apprentice will be £14. A master weaver will receive a certain amount every three months, beginning with about £5 for the first payment and gradually decreasing until in the last quarter of the third year he will receive 16*s*. 8*d*.

The sum of about £10,000 is to be set aside annually for the construction and fitting up of fifty workshop dwellings at about £200 each for Lyons weavers. About £6,400 is to be expended on the gradual transformation of hand-looms into power-looms and the eventual improvement of the latter. Such looms or improvements will be sold to weavers at half price, and the money to purchase them will be lent without interest. About £7,300 is to be devoted to pensions and other aid to aged master weavers and their wives. These various sums mentioned make an aggregate of about £24,500 annually, but will be reduced by repayments of money advanced in the construction of workshop buildings. It is further asked that the proper Government authorities be empowered to order silk textiles for furnishing the national palaces in France, and French embassies and consulates, to the amount of £400,000. This sum will be extended over a period of twelve years from 1911 to 1922, with a privilege of carrying from one year to another any sum not disbursed. It is to be stipulated in giving the orders that wages and amounts for piece-work are to be paid according to the tariffs approved by a council of experts.

Further, the creation is demanded at Lyons of a so-called conservatoire in the interests of the silk industry, in which will be incorporated an atelier for permanent demonstration in the practical phases of silk-weaving. This atelier will serve as well for the instruction of apprentices. An experienced silk manufacturer of Lyons has drawn up the plan in all its details for the new conservatoire. In presenting the project it was called to mind that generations of weavers and employers, of whom a number became manufacturers, sprang from old-time ateliers that took the place of an open technical school. The popularisation of the silk industry and the introduction of the power-loom, with women employed for the weaving, have brought about a gradual disappearance of the large ateliers, and finally of the smaller ones. This

Hosted by Google

circumstance, which caused the creation of the present unpretentious weaving school, is to be the starting-point of the vast atelier, which will be known as a conservatoire of the arts of the silk industry. This will be in a sense a national institution, and will be a means to keep the famous French industry in the forefront of the world's manufactures. In the new conservatoire there will be ten entirely independent ateliers, each one with a hand-loom for making high-class figured silks, with all the necessary departments found in an extensive and thoroughly modern silk-weaving mill. If the new conservatoire is to be apart from the weaving school, a large hall will serve as a museum.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

The Dimensions of the Textile Industries.—A notion of the immense dimensions of the British textile manufacturing industries is obtainable from a comparison of the textile with the agricultural output. Agriculture, traditionally the greatest of British industries, is credited in the latest official returns with a gross output of £150,800,000 during 1908 in Great Britain only. Textile factories were given credit for £327½ millions in 1907. The amount includes the textile productions of Ireland, but the subtraction of these leaves a sum of £314 millions, and the total is confessedly incomplete. Agriculture employs 1,173,000 permanent labourers, and textile work 1,060,500 persons. There was casual labour on the farms which at June 4th, 1908, added 167,000 to the total, and there were half a million occupiers, of whom some must be classed with the permanent workers. With all allowances on this score the sheer magnitude of textile operations will still seem impressively large. This effect is heightened by contrast with the 854,600 at work in and about coal mines in 1907, or the 945,900 engaged in the building trades, recorded in the census of 1901.

The Textile Institute.—These huge proportions imply a large public intimately interested in textile affairs, but by process of specialisation any one person is interested deeply in relatively a small segment of the proceedings. The difficulty of discovering matter of common interest to men engaged in different textile trades or in different branches of the same trade is speedily found by those who address themselves to the whole. This is one of the intrinsic troubles incidental to the working of such a body as the Textile Institute, which set forth a couple of years ago with intent to be to textile industry all that the most successful institutes have been to the metal trades. In part the difficulty has been rounded by making the Institute peripatetic, and holding congresses by turns in Manchester, Bradford, Belfast, and last in Hawick. Every centre of the industry has a life and interests of its own, apart from that shared by districts in common, and only by separate application to each can attention be enlisted. Thus at the Hawick meeting the programme was arranged with an eye firstly to the local interest in tweeds and hosiery, wool and wool yarn, and, secondly, to the universal interest in the respective advantages of steam, gas, oil and electricity as sources of power.

Scotch Tweeds.—Of the papers read at Hawick, that of Mr. Thomas Welsh upon the Scotch tweed manufacture had the widest popular appeal, and his account of the origins and progress of this large and now lucrative industry may prompt others to recall the steps in the evolution of their own. Mr. Welsh attributed the fashion of wearing tweeds to the daring of an obscure innovator, who had an old shepherd's plaid converted into trousers. Shepherd's checks—or "Sheppard's" checks as some say they should be spelt in memory of a deceased weaver — have their periodical vogues still. The black and white commended itself to Sir Walter Scott, and became a regular part of Sunday apparel. The accidental discolouring of the white in one batch of pieces stimulated the owner to dye the goods brown, and the new black and brown caught the public fancy. One colour led to another, and gradual and tentative experiments in design brought into being the infinitely various and complex patterns of to-day. The cloths were worked out first in the wools of the locality, as cheviot cloths are still. Mr. Welsh gives 1833 as the date at which fine foreign wools began to be used, and, although Scotland now receives its fine wool from Australia, the old name Saxony, conferred by the use of Saxony merino, still distinguishes fine cloths from coarser ones. Scotch tweeds owe their renown, half to the unimpaired excellence of their quality and half to the cunning with which their colourings have been devised. For inspiration in colour effects one early manufacturer went to the granite, porphyry and jasper of the Pass of Killiecrankie, while others went to the neighbouring hills for heather and grasses embodying colour contrasts capable of reproduction in dyed wool. The evidences of natural derivation are apparent in the cloths of our own day, but it is simple truth to add that some have a more prosaic origin. Dyers tell of snatches of wall-paper, threads of silk, and even samples of soft soap, sent to them to illustrate the colour or combination that the designer would be at.

Sources of Design.—If the origins of textile colourings are sometimes bastard, so also are the elements of design in ornately figured woven and printed goods. No source is despised, and consequently it is possible to enter a public designer's room and find there picture posters exhibiting the masses and contrasts that one client wishes him to imitate. At another time, vases are sent on loan for the sake of the decorations they exhibit. Picture postcards, supplements of the British and foreign art papers, lithographs, engravings, and, of course, photographs serve to supply raw material. All is fish to the handymen who, in the course of

Hosted by Google

satisfying the home and foreign public taste, have inevitably to descend to depths not approved by masters and amateurs of art. There are two ways of regarding the concessions that are made to public predilections, and it would be wilful to deny recognition to the merits of some of the work that escapes from ateliers that are responsible also for some of the most rococo productions. Public designing for textile purposes is done more largely in France than in England, and there is always an importation into this country, America and Germany, of Parisian designs. French and German designers have been brought in a few cases to English workshops, and their individual or co-operative works have sold to France. Apparently French manufacturers are more concerned at present to get strong and rugged designs than weakly pretty ones. Their own men have more than all the neatness that is required, but lack in the breadth of treatment that is distinctive of some English work.

Cosmopolitan Cloths.—Taste and design are not more cosmopolitan in the textile world than the material part of woven productions. Cotton comes here from America or Egypt to be made into yarn for export to another country where the weaving is done. Some of it, woven into cloth, is sent to Switzerland to be embroidered, or to Holland to be printed, either to be returned here or re-exported to some other market. The case is similar with wool. Bradford receives and combs wool for Germans, Japanese, Scandinavians and Italians to spin, and sends forty or fifty million pounds of worsted yarn to Germany to weave. Belgian woollen yarn arrives in heavy quantities in this country to make Bradford dress goods and Glasgow shirtings, and Belgian cotton yarn sells to a small extent to make Nottingham curtains. Italy has long supplied our manufacturers with spun silk, and now Japan is sending to this market spun waste silk yarn of somewhat uneven quality at a shilling a pound less than the price for which yarn of similar length can be got from other sources. Between the foreign cloths made from British materials and the British-made cloth from imported yarn, the national origins of a large part of the world's production are notably mixed. The export of half-finished goods has been jealously regarded by manufacturers of cloth, and the quick growth of the foreign trade in the less advanced productions has pointed many complaints as to the state of the industry. But cloth, in the overwhelming majority of instances, is not a fully-manufactured commodity, and until it becomes a robe or a suit is not complete for consumption. Thus, if the cloth manufacturer has his grievance against the export of yarn, so also has the clothing manufacturer against the export of cloth. Both here and abroad manufacturers find they can weave that which they cannot economically spin or get spun in their own countries. Yarn production is increased by spinners, more or less, in accordance with the demand, and without reference to the nationality or situation of those who will do the ultimate weaving or knitting.

The Carpet Industry.— The manufacture of carpets, although closely associated with woollen and worsted manufacture at large, constitutes a fair-sized *imperium in imperio.* At any rate, two of the large carpet mills in this country have undergone recent extension on a considerable scale, and the export of carpets continues to expand. No doubt the gross production of this branch has increased since 1907, when it was returned at appproximately £4 millions. Nearly one-fourth of that total has been recorded already in the export returns for the first eight months of this year. Canada, which has its own carpet works, some of them in the ownership of Kidderminster firms, and Australia, are at present the principal oversea markets. Extensive additions have been made to a mill already large, owned by a Yorkshire firm in the United States. Apparently seamless squares in Wilton, chenille Axminster, and other Axminster makes, are proving profitable to manufacturers, and their popularity is manifest in the homes and the shops. The dominance of the taste for Oriental colourings and designs is marked strongly in all forms of pile carpet. More independence is shown in the Roman or art squares both in the matter of decoration and colour. Self-coloured mohair rugs, made by plush manufacturers, have established their place among the productions of the carpet mills proper. The carpet trade is good, despite the incessant advances of its great competitor, linoleum.

NOTES ON BOOKS.

Signatures in the First Journal-Book and Charter-Book of the Royal Society. Record of the Royal Society. Printed for the Royal Society. London. 1912.

These two handsome volumes were published in commemoration of the 250th anniversary of the foundation of the Royal Society of London. The first-named is specially interesting and valuable, because it contains facsimiles of the signatures of all the Fellows of the Royal Society from its foundation to the present time, with the exception of course of the comparatively small number of those who never signed the Charter-Book, every page of which has been carefully reproduced by photography and reprinted in the original size.

This edition of the Record Book is a reproduction, with additions, of the work which first appeared in the year 1897, the object of which was "to provide a compendium of information, largely historical, regarding the rise and progress, the organisation and work of the Royal Society." It was originally proposed that new editions should be issued every five years, but eventually it seemed that this was unnecessary, much of the information being given

Hosted by Google

in the Society's Annual Year-Book. A second edition was published in 1901, and the present is the third. It contains a chapter on the foundation and early history of the Royal Society, the Charter and Statutes, the Trusts, and full information about the Society's committees, publications, and the funds which it administers. There are also lists of the medallists, and some account of the relics, portraits, busts, and medals in the possession of the Society. There are two lists of the Fellows —one in chronological and the other in alphabetical order.

It will be seen that this Record to a large extent supplies the need which has often been remarked upon for a complete history of the Royal Society. There are actually four histories of the Royal Society, but none of them of modern date. The first by Thomas Sprat, Bishop of Rochester, which was published in 1667, although it contains a certain amount of information, was rather a defence of the Society against attacks of the *a priori* philosophers than a true history. Birch's history, published in 1756, leaves off at 1687. It is rather a history of scientific progress in England during the latter part of the seventeenth century than of the Royal Society itself, though it gives an account extracted from the manuscript records of the subjects brought before it, and is no doubt a work of very great value. Thomson's work appeared in 1812—it was valuable chiefly for the lists of Fellows contained in it, and in this it has now been superseded. Weld's history of the Royal Society, published in 1848, is perhaps the book upon which everyone who would study the past history of the Society has to rely. But it does not bring the narrative down beyond 1830, and the copious materials which his industry collected are ill-digested and ill-arranged. There are, of course, short accounts of the Royal Society to be found in the various encyclopædias—the one in Knight's English Cyclopædia is specially interesting, because it is believed to have been written by Professor De Morgan.

Full material for a history is to be found in the annual presidential addresses which are printed in the Royal Society's proceedings, and it would be an interesting piece of work if anyone would take the materials contained in them, in the Record, and in the histories above referred to, and would produce from them a fairly compendious history of the Royal Society down to the present date.

Parallel Paths. By T. W. Rolleston. London: Duckworth & Co. 2*s*. 6*d*. net.

Mr. Rolleston's study in biology, ethics, and art was first published in 1908, and its reappearance in its new and cheap form is to be warmly welcomed. There is no need to criticise the matter of the volume at the present day, for the author's well-known philosophical insight and scientific learning have won it a well-recognised position in the world of books. One may, however, offer a word of congratulation to the publishers on the Readers' Library, of which this volume forms a part. The series now contains a number of works of remarkable interest; the books are excellently printed, they are bound in a tasteful and workmanlike style, and offer excellent value for the very modest price asked for them.

The Origin and Evolution of Primitive Man. By Albert Churchward, M.D., M.R.C.P., F.G.S. London: George Allen & Co., Ltd. 5*s*.

This little volume is a reprint, with some additions, of a lecture delivered by the author at the Royal Societies Club last winter. Dr. Churchward is fully convinced that "the preconceived ideas of many scientists as to the origin of the human race—as regards both time and place—are erroneous." He himself would place the cradle of the race in central Africa, and primitive man in the Pygmies, who, he thinks, are not a degenerate race, but an undeveloped one. The evolution of man he traces from this source through the Bushmen, the Masaba Negro, the Nilotic Negro, the Masi, the Mongoloids, to the so-called Aryanists.

Dr. Churchward has evidently devoted much attention to the study of the Pygmies, their anatomy, their customs, beliefs, and language, and what he has to say about them is extremely valuable. A large number of illustrations add materially to the interest of the lecture.

GENERAL NOTES.

Public Health Research.—At the close of this month the extensive new laboratories of public health and bacteriology, recently formed by the Charing Cross Hospital Medical School, and taken over by the University of London as the public health and bacteriological department of King's College, will be formally opened and handed over to the University. The laboratories are situated in Chandos Street, Strand. They include a large class laboratory, research, professors' and lecturers' laboratories for the departments of public health and bacteriology respectively, preparation and animal rooms, a large theatre, and a library for the joint use of the two departments. The regular courses of instruction in bacteriology, clinical pathology, and photomicrography, and for the diploma of public health, will be given there, and research and investigation work for public bodies and others will also be carried on.

Rubies.—Mr. Noel Heaton, who, it will be remembered, read an extremely interesting paper on "The Production and Identification of Artificial Stones" before the Society some eighteen months ago, has written a small pamphlet on "Rubies," which is published by the Burma Ruby Mines, Ltd. He briefly explains what a natural ruby is, and how it may be distinguished from other similar stones, and especially from reconstructed

Hosted by Google

and synthetic rubies. Some excellent coloured illustrations demonstrate the differences between the various kinds of stone with great clearness. A case recently tried in the law courts showed what extraordinary confusion on the points dealt with by Mr. Heaton exists even in the minds of those who are supposed to be experts on the subject, and the pamphlet should prove of great service to jewellers and dealers in precious stones.

THE U.S.A. HARVEST. — The reports of the harvest in the United States of America continue to be very favourable. Dr. Henry Clews, the well-known American financier, writes: "A total wheat crop, closely approximating 700,000,000 bushels, is now reasonably assured, which is a total that has but twice been exceeded, namely, by the 735,000,000 bushel yield of 1906 and the 748,000,000 bushel harvest of 1901. Spring wheat this year is making a magnificent showing, being estimated at 300,000,000 bushels, which compares with a yield of 190,682,000 bushels in 1911. This excellent showing more than compensates for the poorer showing of the winter wheat crop, which resulted from the unusually severe winter of 1911–12. Oats and hay are far in excess of the yields of earlier years, which will, of course, release for export a considerable amount of corn that would otherwise have been required for feed on the farm. Cotton cannot be expected to approach the extraordinary yield of last year, but according to present promises, will probably not fall far short of 14,000,000 bales, if, indeed, it does not exceed that total."

THE SMOKE NUISANCE.—A bulletin recently published by the Department of Industrial Research, University of Pittsburgh, gives some interesting details of an investigation which is now being carried out in that city into the smoke nuisance. The Director of the Department, Professor Robert Kennedy Duncan, who is a distinguished member of this Society, has received from a private donor a fund for the purposes of the investigation. At the present moment the inquiry is being conducted by a staff of twenty-five specialists, six of whom are giving their entire attention to the work, while the remaining nineteen have been entrusted with the preparation of special reports concerning particular phases of the subject. Among these are such questions as the effect of smoke upon weather, upon vegetation, the chemistry of smoke and soot, the deterioration of buildings and building materials in smoky atmospheres, smoke and disease, the cost of the smoke nuisance, the question of legal regulation, etc. Under the direction of Professor Duncan, the investigation will, no doubt, be extremely thorough, and the results ought to prove of great value. Not the least interesting part of the work will be an attempt to educate public opinion in the matter. It is proposed to make a systematic effort to enlighten civic and business organisations, and to arouse them to combined action. A staff of lecturers will be organised to address such organisations in Pittsburgh and elsewhere; efforts will be made to secure the co-operation of the public press, and finally the results of the whole inquiry will be published in book form.

DEMAND FOR ITALIAN-MADE GOODS IN SOMALILAND.—According to a communication recently received by the Administration of the Commercial Museum (*Museo communale*) of Milan from the Italian authorities at Mogadisco (Somaliland), there appears to be a demand for Italian-made goods in that country. Amongst the principal articles which are required by the government of the colony at the present time, may be mentioned building material, bricks, cement, timber, ironwork, ironmongery of every description, rails and material for light railways, motors, agricultural, pumping and other machinery, paint and varnishes, printing material, stationery, rope, cordage, cotton goods, etc.

THE COMMERCE OF NAPLES.—The value of the export and import trade of Naples has increased considerably during the last three years, as will be seen by the following statistics recently published by the Chamber of Commerce at that port—

Exports.

	Lire.	£ sterling.
1909	99,648,989	3,985,959
1910	111,299,000	4,449,960
1911	161,484,510	6,459,380

Imports.

	Lire.	£ sterling.
1909	248,712,010	9,948,480
1910	265,499,256	10,619,969
1911	290,846,560	11,633,862

This shows an increase in the value of the exports of 50,185,510 lire (£2,007,420), and of 25,347,304 lire (£1,013,892) in the imports of 1911 as compared with 1910. The exports last year were chiefly macaroni and other kinds of Italian paste, to the value of (in round numbers) eighteen million lire (£720,000); fruit and vegetables preserved in salt, oil or vinegar, fifteen million lire (£600,000); manufacture of coral goods, fifteen millions (£600,000); preserved tomatoes, ten millions (£400,000); cheese, ten millions (£400,000); cattle, eight millions (£320,000); raw hemp, seven millions (£280,000); manufactured tobacco, five millions (£200,000); flour, dried fruit and wine, four millions (£160,000) each. The imports during the same year consisted principally of grain to the value of forty-four million lire (£1,760,000); hard wheat, used exclusively for the manufacture of macaroni, thirty-eight millions (£1,520,000); coal, twenty-two millions (£880,000); cotton, fifteen millions (£600,000); dried fish, twelve millions (£480,000); machinery and parts of machines, eleven millions (£440,000); raw hides, nine millions (£360,000); copper and its alloys, in ingots, seven millions (£280,000); iron and steel plates, five millions (£200,000); sulphate of copper, dressed hides and cotton goods, four million lire each (£160,000).

Journal of the Royal Society of Arts.

No. 3,125. VOL. LX.

FRIDAY, OCTOBER 11, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICE.

"OWEN JONES" PRIZES FOR INDUSTRIAL DESIGN.

The Council of the Royal Society of Arts hold a sum of £400, the balance of the subscriptions to the Owen Jones Memorial Fund, presented to them by the committee of that fund in 1876, on condition that the interest thereof be spent in prizes to "Students of Schools of Art who, in annual competition, produce the best designs for household furniture, carpets, wall-papers and hangings, damasks, chintzes, etc., regulated by the principles laid down by Owen Jones."

Competitions under the terms of this Trust have been held annually since 1878.

The next award will be made in 1913, when six prizes are offered for competition, each prize to consist of a bound copy of "The Leading Principles in Composition of Ornament of Every Period," from the "Grammar of Ornament," by Owen Jones, and the Society's Bronze Medal.

The prizes will be awarded on the Report of the Examiners in the National Competition of the Board of Education. The designs must be submitted in the usual manner to the Board of Education by April 1st, 1913. They must be marked "In Competition for the Owen Jones Prizes," and must comply with the regulations of the Board of Education. The exact address to which the work should be sent will be communicated later to the schools by the Board of Education.

No candidate who has gained one of the above prizes can again take part in the competition.

In the competition held in 1912, 490 works were submitted, the best examples being in woven, printed and stencilled fabrics. Some good designs in damasks, carpets, embroidery and lace were also submitted.

PROCEEDINGS OF THE SOCIETY.

HOWARD LECTURES.

HEAVY OIL ENGINES.

By Capt. H. Riall Sankey, R.E. (Retired), M.Inst.C.E.

Lecture II.—Delivered May 6th, 1912.

Design of Diesel Engine.

As already stated, the essential part of the Diesel engine is the fuel valve, and it requires special design; the other valves are like those adopted for gas engines, and the method of driving them is substantially similar. All the other parts, a list of which will be given later, are similar to the corresponding parts of a steam or of a gas engine, and in a general way their design follows that adopted for those engines.

The differences are mainly those of dimensions, brought about by the far greater pressures that have to be withstood. As regards the cylinder, in the case of a steam engine the high-pressure cylinders have to be designed for working pressure of from 150 lbs. to 200 lbs. per square inch, whereas, both in gas and Diesel engines, working pressures of at least 500 lbs. per square inch have to be considered.

The dimensions of connecting-rods and crank shafts depend on the maximum forces applied to them, and not on the average forces, and both in gas and Diesel engines the ratio of the maximum to the mean force is far greater than in the case of the steam engine; this leads to greater scantlings. Occasionally, however, the parts of all these engines may have to withstand much higher stresses, due, in the case of the steam engine to water hammer, in the case of the gas engine to pre-ignition, and in the case of the Diesel engine to a charge remaining in the cylinder unignited and causing an explosion at the top of the next stroke, thus increasing the

Hosted by Google

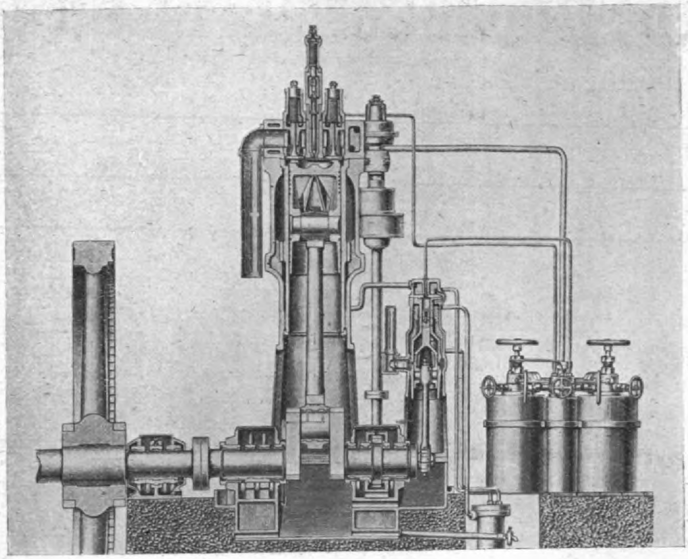

FIG. 15.

The large number of different designs that can be produced by combining two or more of these various types is obviously very great, and at present the process of selection is going on.

There would not be time to go seriatim through all these various types, but a few of them will be described in a general way and illustrated later. A good idea of the general design can be obtained by studying the more usual arrangement adopted for a single line vertical four-stroke slow-speed Diesel engine of 100 B.H.P., of the kind now being manufactured by a very large number of firms in this, and other countries.

In this design the engine is single-acting, and the piston is of the variety known as a trunk piston, which also acts as a guide, so that no piston rod or cross-head guide is required, and the cylinder can be placed much nearer to the crank shaft, thus reducing the height of the engine materially.

The vertical section of such an engine is

pressure to about 1,700 lbs. per square inch. So long, however, as the stress thus produced is sensibly below the elastic limit of the material no harm will be done.

It will be gathered from the above that the thickness of cylinder walls, the strength of cylinder covers, studs for securing the cylinder covers to the cylinders, the framework generally, the connecting-rods, and the crank shaft, will be much greater in the case of the Diesel oil engine than in a steam engine of equal power running at the same speed. These increased scantlings of the Diesel engine produce a feature which immediately attracts attention.

Apart from the power to be developed, the design and dimensions depend also on the type of Diesel engine under consideration, and these may be classified as follows:—

- Slow speed, 100 to 200 revolutions per minute.
- High speed, 300 to 600 revolutions per minute.
- Vertical or horizontal.
- Four-stroke, single acting or double acting.
- Two-stroke, single acting or double acting.
- One, two, three or more lines (an eight-line engine has already been constructed).

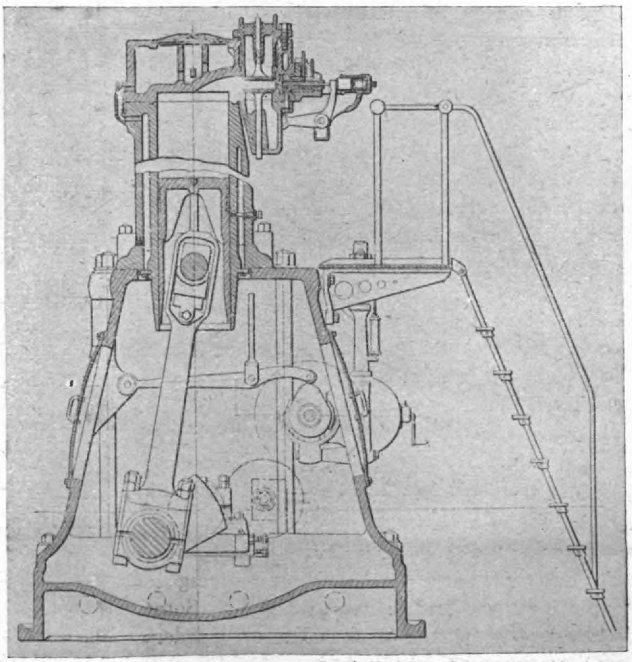

FIG. 16.

Hosted by Google

given in Figs. 15, 16, 17, and 18, and the various important parts are as follows:—

1. The base.
2. Bearings.
3. Lubricating pump.
4. Crank shaft.
5. Fly-wheel.
6. Framing.
7. Connecting-rod and its bearings.
8. Trunk piston.
9. Piston rings.
10. Cylinder and jacket.
11. Cylinder cover.
12. Two-to-one shaft.
13. Levers for actuating valves.
14. Special air valve levers for starting.
15. Fuel valve.
16. Exhaust valve.
17. Air suction valve, and pipe.
18. Air-compressor.
19. Compressed-air vessels.
20. Fuel pump.
21. Fuel tank.
22. Governor and its drive.
23. Exhaust pipe and silencer.

In the design shown in Figs. 15, 17, and 18, the walls of the jacket cylinder form part of the framework of the engine, thus connecting the cylinder cover through the A frame to the base and making a fixed link in the kinematic chain, known as a slider crank chain, to which all such reciprocating engines belong. In Fig. 16 the jacket cylinder is bolted to the A frame, or rather to the crank chamber. The former is the more usual design for slow-speed engines, and is adopted by Sulzer, Willans and Robinson, Burmeister, and Wain, and many other builders, even for large engines; and in this case the engine is not enclosed, the A frame itself forming the necessary shield to prevent the splash of the lubricating oil. There does not seem to be any special reason for adopting a closed crank chamber in the case of slow-speed engines, and the open frame has many advantages, such as easier inspection whilst running, greater ease in getting at parts for repairs, and greater ease for the heat to radiate, thus keeping the bearings cooler. In the cases referred to above, the cylinder proper is formed as a liner, and can be removed by taking off the cylinder cover and

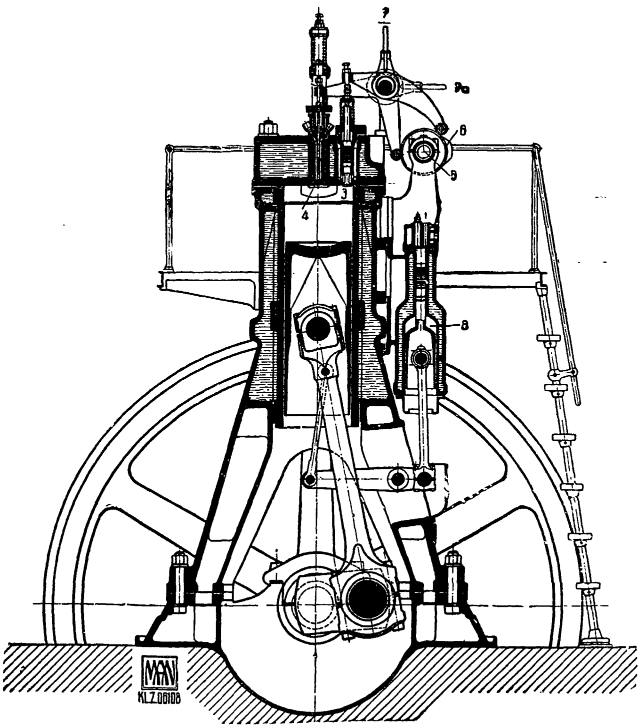

Fig. 17.

Each of these parts will now be considered in the order named, and at the same time some of the modifications that are made by various constructors will be described.

without dismantling the engine. In some cases the cylinder and liner are formed in one casting, bolted to the A frame or to the crank chamber, as, for example, in the marine engines made

Hosted by Google

by the Maschinenfabrik Augsburg - Nürnberg Company.

1. *The Base.*—This is in the form of a box-casting, with holes through it for bolting to the foundations. There are facings machined to take the flanges of the A frame or crank chamber, and seatings are machined for the bearings. In engines of 1,000 h.p. and upwards, Messrs. Krupp, Sulzer, and Carels, make the base in segments, bolted together *in situ.*

3. *Lubricating Pump.*—When forced lubrication is used, which is the arrangement adopted with closed crank-chambers, practically any type of forced lubrication pump will do. The various makers have their own design on which they rely. The oil pipes connecting the lubricating pump to the various bearings are usually made of copper. The oil flows back into the base, and after being strained returns to the pump. Some makers have an independent pump for

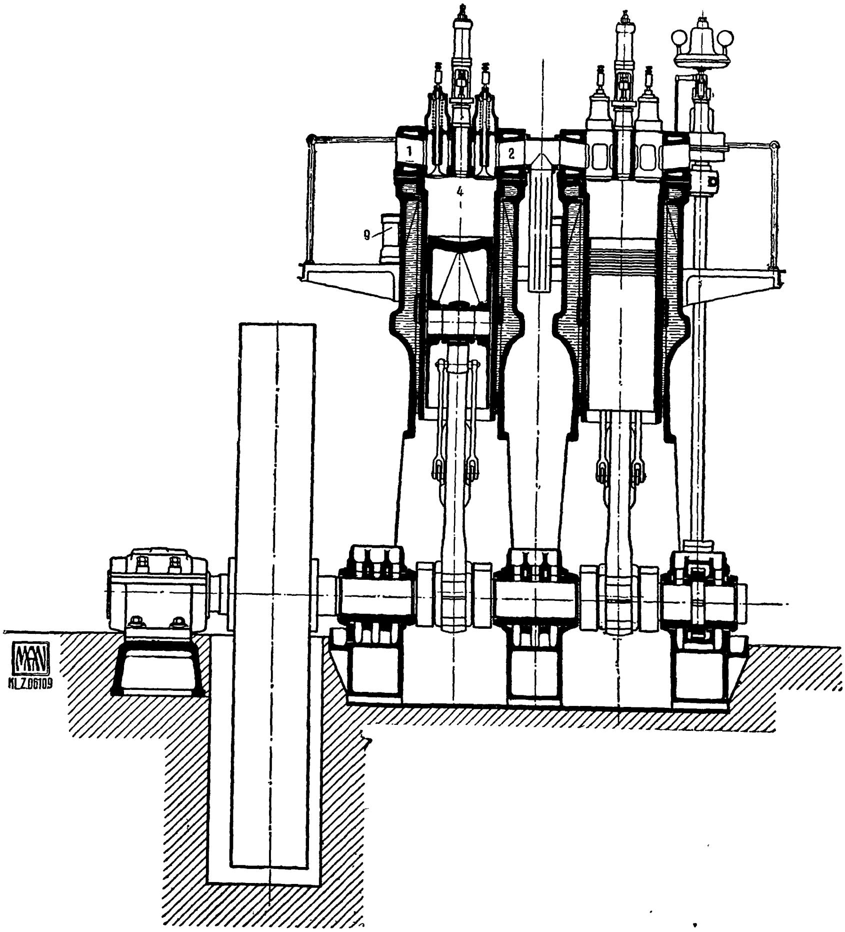

FIG. 18.

2. *Bearings.*—The bearings for the crank shaft are usually of white metal in cast-iron or steel shells. The white metal is continuous over the whole bearing, and the shell must be carefully tinned so as to obtain good metallic contact between the white metal and the shell, in order to reduce the heat resistance which would otherwise exist between the surfaces of the two metals, so as to conduct away the heat which is produced by the friction of the bearings.

lubricating cylinders, in which case the oil is forced through small holes at the base of the liner at the end of the working stroke. The bearings at both the big and small end of the connecting-rod are forced lubricated, but in small and medium engines the crank shaft bearings are lubricated by means of a ring; in large engines these bearings are also forced lubricated.

4. *Crank Shaft.*—Forged nickel steel is used by many makers. As already pointed out, the

Hosted by Google

crank shaft of the Diesel engine is subject to greater inequality of torque than that of the steam engine; it is also subject to heavy shearing stresses, and in the case of single-acting engines to reversal of stress. Thus much larger diameters are required, in the same way as was found to be necessary in the case of the Willans' engine, and the effect may be gathered from the following. A shaft transmitting 100 h.p. at 200 revolutions per minute by pure torque, *i.e.*, when there is no bending stress, should be 2·6 in diameter; but when exposed to the maximum bending stresses likely to occur in practice, the diameter must be increased to 4 ins., and the latter may be taken as the conditions of working for an ordinary steam engine crank shaft. To meet the requirements of the Diesel engine, as stated above, the diameter of the shaft should be at least 10 ins.

5. *Fly-wheel.*—The fly-wheel of a Diesel engine, like that of a gas engine, must contain sufficient energy to maintain the velocity fairly constant in spite of the want of uniformity of torque indicated in Fig. 14. Four-stroke engines require larger fly-wheels than two-stroke engines, and the fewer the cylinders the larger the fly-wheel must be. To give some idea of the size of the fly-wheel, it may be stated that a two-line four-stroke 250 B.H.P. engine, running at 200 revolutions per minute, requires a fly-wheel weighing fifteen tons, and since the weight of the engine itself is forty tons, it will be seen what a large proportion the weight of the fly-wheel bears to that of the rest of the engine. The stored energy in this fly-wheel is 4,320,000 foot lbs., or at the rate of about 17,000 foot lbs. per B.H.P.

Owing to the want of uniformity of the torque, the fixing of the fly-wheel shaft has to be effected with special care.

6. *Framing.*—In Figs. 15, 17, and 18 the A frames are of cast-iron box section, often fitted with splash-guards, and this is the usual construction with slow-speed engines. Sometimes a single casting, forming a crank chamber, takes the place of the A frames when an engine has several lines; this is always the case with high-speed engines. Facings are machined at the feet to marry with the facings machined on the bed, and if the jacket cylinders are separate, facings have to be machined on the top of the A frames as well.

7. *Connecting-rods.*—Solid forgings of good quality carbon steel are used; the big end for land engines is generally of the flat-footed type to bolt on to the big end-bearings or brasses. These brasses are often made of phosphor bronze, but many makers use steel shells lined with white metal. The small end is often slotted out to carry a special split phosphor bronze bearing, and a screw adjustment is fitted so that the length of the connecting-rod can be altered within small limits to adjust the compression accurately. When an open A frame is used, the lubrication of the small end is effected by means of a hole drilled through the gudgeon pin, which comes opposite a slot in the cylinder at the bottom of the stroke, and at this moment the lubricating pump squirts in a supply of oil. For the smaller engines a connecting-rod of circular section is used; for high-speed engines, in order to obtain lightness and better distribution of the material, a round section with flattened sides is employed, and some makers have even gone to the expense of using flat rods milled out so as to obtain an H section, which, of course, is theoretically the best section for resisting the transverse inertia stresses. Such a section, however, can only pay commercially with high speeds and when great lightness is a necessity. The big end-bearing bushes are of similar design to those adopted for steam engines, the only difference being their greater weight for the same horse-power.

8. *Trunk Piston.*—The trunk pistons are made of cast-iron, generally in one casting; they are ribbed inside for strength and for cooling, and a through hole is provided for carrying the gudgeon pin of the connecting rod, as shown in Fig. 16. The top is generally curved so as to relieve the stresses produced by the heat, and this shape of top has probably the effect of producing eddies, which increase the rapidity of combustion. This question of eddy-forming or turbulence is one which has only recently been noticed, and some experiments made a short time ago by Mr. Dugald Clerk and Dr. Bertram Hopkinson showed that in the case of the gas engine it is a most important factor in promoting rapidity of explosion. This is a matter which will have to be studied more closely in connection with the Diesel engine.

The maximum diameter of trunk piston that can be safely run without water- or oil-cooling is 24 ins. Above this diameter it is necessary to arrange for a water circulation or for an oil circulation. Messrs. Sulzer adopt an arrangement whereby oil is squirted on to the under side of the piston at the top of the stroke; the oil then falls in a shower into a cup, whence it is conducted to the connecting-rod to lubricate the small end.

Hosted by Google

The piston body is grooved for the piston rings, and is extended to form a guide. There are also grooves without rings placed at the bottom of the extension, to hold the lubricating oil. Messrs. Krupp and Messrs. Sulzer water-cool the top end of the piston in large engines, and have adopted an arrangement which gives no dynamical action, and there are no glands on the pipes. The large marine engines of the Maschinenfabrik Augsburg-Nürnberg Co. are oil-cooled. The gudgeon pin is made of case-hardened steel, and is fixed in the piston body. Special care has to be taken to ensure that it is accurately placed in the piston body so as not to produce any cross strains, either in the piston or in the connecting-rod, and these arrangements have to be such that the pin can be easily withdrawn

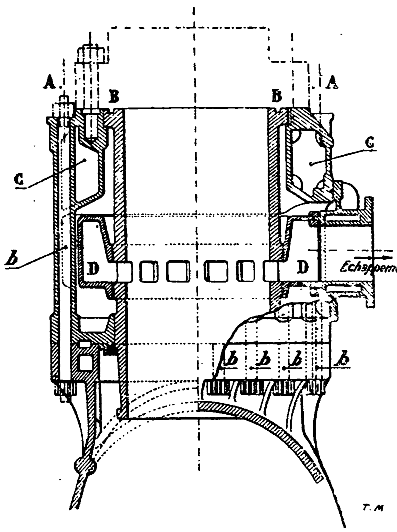

Fig. 19.

for repair or renewal. Usually the length of a trunk piston is 1·8 times the diameter. A considerable clearance has to be allowed between the piston body and the cylinder; only experience can tell what this amount ought to be.

9. *Piston Rings.*—These are of the usual Ramsbottom type placed in the grooves in the piston body. Messrs. Sulzer adopt a special arrangement for machining these piston rings to get uniform pressure at all points; it is the same arrangement which they have adopted for years for steam engine piston rings.

10. *Cylinders and Jackets.*—The general design of these has already been referred to, and can be seen from the figures.

When the jackets are separately cast they are flanged at the lower end to bolt to the top of the A frame. Great care must be taken to machine these facings truly perpendicular to the axis, else difficulties will arise in running the engine. The studs have to be very large; in the case of a 20-inch cylinder, for example, eight studs, $2\frac{1}{2}$ inches diameter are required. A special cast-iron mixture, suitable for resisting high temperature, is required for the cylinder liners.

11. *Cylinder Cover.*—The cylinder cover is cast with the water-jacket, and is arranged for taking the valve seatings of the air, fuel, and exhaust valves. There are through holes in the cover to take the long studs fixed in the top of the jacket.

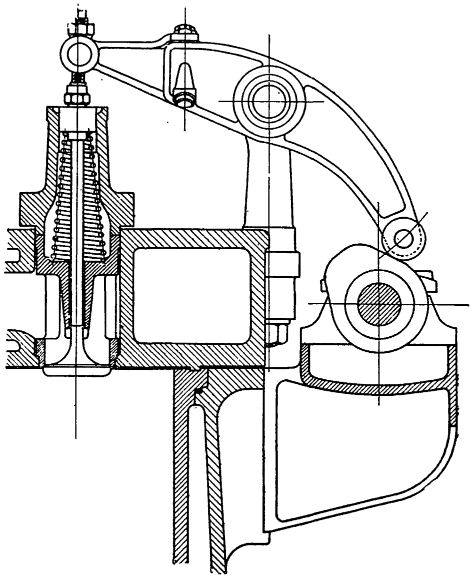

Fig. 20.

Fig. 19 shows a form of construction recommended by N. Brosne for cylinders in order to minimise the effect of the exceptional stresses due to possible explosion (instead of combustion), which may cause pressures of from 100 to 150 atmospheres in a cylinder. The cylinder head consists of a flat plate stiffened by radial and circumferential ribs arranged so that the seatings of the various valves can be placed between them. The head is closed over with a light steel cover, thus forming a space for the water circulation. There is a stiff ring of hollow section placed around the top of the cylinder and carrying the studs for bolting on the cylinder cover. This ring is connected to the framework by long steel bolts which, by their elasticity, take the shock of any exceptional explosion, and at all times relieve the cylinder walls of

Hosted by Google

tensional stress, a matter of importance in two-stroke engines having exhaust openings through the cylinder walls at the bottom of the stroke when these walls carry the stresses.

12. *Two-to-one Shaft.*—The two-to-one shaft, or cam shaft, which is, in most engines, fitted in bearings carried on brackets, either bolted or cast with the jackets, approximately at the level of the top of the cylinder, is driven by helical gear from the crank shaft by the intermediary of the vertical shaft, the gearing being such as to reduce the speed in the proportion of two to one, so as to give a proper sequence for the four-stroke cycle. In some cases the cams are ground to the proper shape after being keyed on the shaft; other makers grind the cams to a "former," and thus obtain satisfactory results. In some of the larger engines the two-to-one shaft is run in an oil bath. In the American type of engine the cam shaft is placed inside the engine, as shown in Fig. 16. In the marine Maschinenfabrik Augsburg-Nürnberg engine the cam shaft is placed on the top of the engine, but in this case it is a two-stroke engine, and the cam shaft runs at the same speed as the crank shaft.

13. *Levers for Actuating the Valves.*—Ordinary levers of the first order are used; they have to be very stiff, as the forces at work are considerable, and there must be no perceptible deflection, or else a true opening in the valve would not be obtained. At the cam shaft end there is a roller, and at the valve end a rocking pin with a round-end bearing in a cup on the top of the valve spindle. These levers are made of cast-iron or malleable cast-iron or of steel. In many designs a hinge is arranged so as to

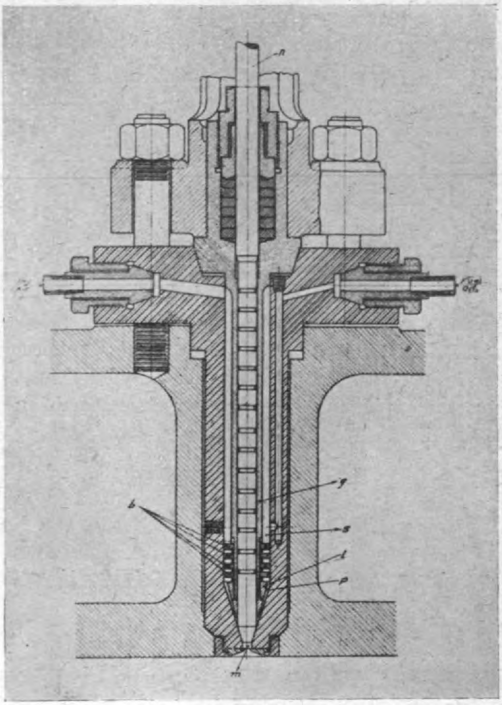

FIG. 21.

throw back the lever when it is desired to lift the valve; this is an important detail for overhauling, and is illustrated in Fig. 20.

14. *Special Lever for Starting.*—This lever works the air valve, which is fixed generally to only one cylinder. Whilst the engine is running it is out of action; for starting the engine its roller is brought into contact with a special cam, by means of a lever, and is thrown out of action again so soon as the engine begins to work on oil.

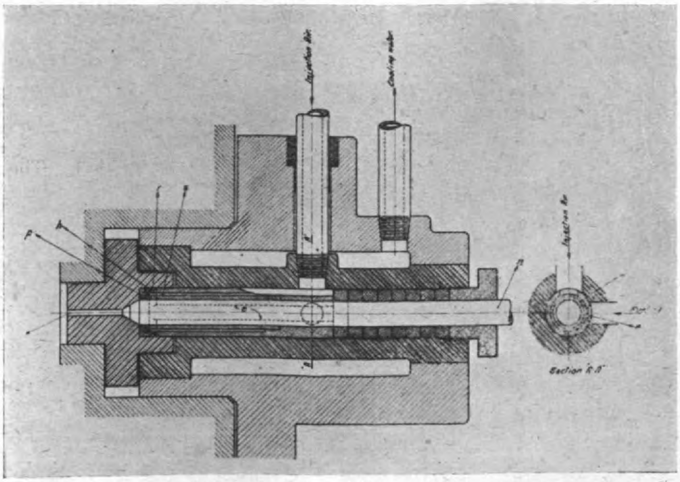

FIG. 22.

15. *Fuel Valve.*—The details of these valves vary, but in all of them arrangements are adopted to break up or pulverise the oil by violently blowing it against surfaces placed opposite to small holes; thus, as shown in Fig. 21, a series of discs having numerous holes are slung on to a central stem, the holes are staggered so that those in one disc are opposite the spaces in the holes of the next disc. At the bottom of the row of

Hosted by Google

discs there is a grooved conical casting fitted into a cone through which the pulverised oil has to rush, and thence through a small hole at the bottom of the valve casing placed on a level with the cylinder top, and which is closed at other times by a needle valve. The lift of the needle valve is only about $\frac{1}{500}$ in.: great care is therefore necessary in fitting the levers actuating the fuel valve.

The fuel valve of the American Diesel engine is shown in Fig. 22, and it is placed horizontally. As the injection valve opens, air and oil, being divided into small streams by a circle of holes, are forced into the injection nozzle, where these streams impinge upon each other, thus atomising the fuel.

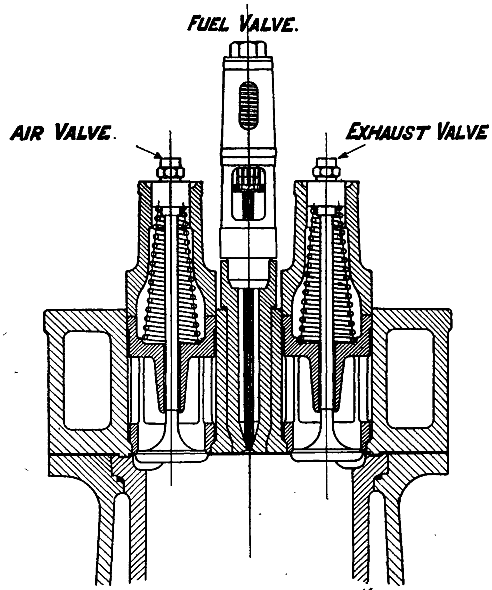

FIG. 23.

16. *Exhaust Valve.*—The exhaust valve is an ordinary mushroom valve, opening into the cylinder and held against its seat by a spring, as shown in Fig. 23, and opened by the exhaust lever at the proper point of the stroke, viz., at about 75 per cent. This valve is allowed to close at about 1 per cent. after the dead centre.

17. *Air Suction Valve.*—This is substantially the same as the exhaust valve (see Fig. 23). It opens 4 per cent. before the upper dead centre, and closes 2 per cent. from the bottom dead centre. Both the exhaust and air valves have their own seating, which is secured into the cylinder cover. This permits of harder cast-iron being used for the valve seatings, and assists overhauling and cleaning of the valves, because the valve and its seating can be bodily removed and replaced by spares. The valves open inwards into the cylinders, and are held on their seats by springs; as already stated, they are opened by means of rocking levers.

18. *Air-compressor.*—The air-compressor has to be capable of compressing air up to 1,000 lbs. per square inch, and must therefore be at least of the two-stage variety; many makers, however, such as Carels and Sulzers, adopt a three-stage compressor. Between the stages the air is cooled. The compressor is driven from the end of the crank shaft by a crank; usually it is of the reciprocating type, either vertical or horizontal, and in many cases the Reavell type of compressor is used, as in the Willans-Diesel engines. It is a vital part of the engine, and is probably one of those most likely to give trouble.

19. *Compressed - air Vessels.* — There are generally three of these vessels, or storage bottles; two to act as reservoirs for starting the engine, and a smaller one acting as an air vessel on the compressor to keep the pressure steady. They should be placed as close as possible to the engine, and are connected thereto by copper pipes. There is a gauge to show the pressure of air being delivered to the engine, which varies from about 950 lbs. per square inch for full load to 750 lbs. per square inch for quarter load. If, however, the load is varying continually the pressure must be maintained for the maximum load. The object of reducing the pressure is as follows—a definite air supply is required for burning the oil; this air is partially supplied by the air compressed in the cylinder and partly by that injected to pulverise the oil. At light loads less air is needed than at heavy loads, and, as the air compressed in the cylinder is constant in amount, that introduced by injection must be reduced, which is effected by reducing the pressure. The two starting vessels are connected to one of the engine cylinders, and the connection is made by a special lever and cam as already described, and the compressed air is admitted at each stroke until firing takes place.

Water collects in the storage bottles, and therefore drainage should be provided. The air supply is more than three times that theoretically required, and the supply is the same whether the engine is running fast or slow; a point which is of interest only for marine engines.

20. *Fuel Pump.*—The designs shown in Fig. 24 consist of an ordinary plunger pump worked by an eccentric off the two-to-one shaft. On the plunger lifting, the foot valve opens and oil is sucked in; on the return stroke the foot valve is held open by the governor until just sufficient oil remains to deal with the load then

Hosted by Google

on the engine. This quantity of oil is then forced through the fuel valve. Makers disagree as to whether each cylinder should have its own fuel pump, or whether one larger fuel pump should be supplied for all the cylinders. In the former case, the casing of the pump contains a plunger for each cylinder, each with its own delivery; in the other case the oil is delivered into a chamber, from which copper pipes lead to the fuel valve of each cylinder, with an adjusting valve, so that each cylinder will get the same amount of oil.

21. *Fuel Tank.*—A small tank is provided with sufficient head for the oil to flow by gravity to the fuel pump. The casing should be warmed to make the oil more fluid, and this can be done by means of the exhaust. The oil is pumped from barrels, or from a storage tank, into the fuel tank by means of a hand pump.

22. *Governor.*—The usual centrifugal loaded type of governor is used, driven from the vertical shaft already referred to, and it acts on the foot valve of the fuel pump. There is generally an arrangement, actuated by a small hand-wheel working on a spring, as shown in Fig. 24, for altering the setting of the governor, by means of which the speed of the engine can be varied from 5 to 10 per cent. whilst the engine is running.

23. *Exhaust Pipe.*—Heavy cast-iron breeches pieces are taken from each cylinder exhaust and connected into one pipe; these are led generally downwards to a large silencing vessel. The pipe then rises again, and can be fitted at the top with any ordinary baffle type of silencer.

The ordinary slow-speed Diesel engine weighs from 500 lbs. to 600 lbs. per B.H.P., as against 100 lbs. per B.H.P. for a steam engine of the same number of cylinders, of the same power, and running at the same speed. In the case of the steam engine, however, the weight of the boiler and accessories, such as condensers, feed pumps, air pumps, etc., must be added, and this weight is approximately 250 lbs. per B.H.P., or a total of 350 lbs. per B.H.P.

By increasing the speed and lightening the scantlings, as is done with the engines used in torpedo boats and submarines, the weight of the Diesel engine has been reduced to about 50 lbs. per B.H.P., or even less.

The above description refers specially to vertical engines, but comparatively recently the Maschinenfabrik Augsburg-Nürnberg Co. have placed on the market a horizontal Diesel engine. According to Dr. Diesel, this, at first, was merely a vertical engine placed on its side; the more recent examples, however, are substantially the same as the horizontal gas engines of the well-known make of the Maschinenfabrik Augsburg-Nürnberg Co., and according to these makers the horizontal engine really becomes of advantage after about 500 B.H.P. The main reasons for preference are based on the facilities for overhauling, and there is the further advantage that cylinders can be readily placed in tandem. The design of the tandem double-acting Diesel oil engine is almost indistinguishable from that of their horizontal double-acting gas engine; the exhaust valve is the same, the air gas valve is replaced by an air valve, and the sparking plugs by the fuel valve. In the

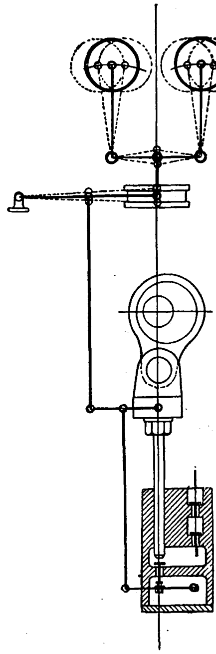

Fig. 24.

case of this horizontal Diesel engine the valves are actuated by cams, whereas, in the case of the gas engine, eccentrics are used in combination with variable fulcrum levers. This difference in valve driving is, however, to a great extent, a matter of taste.

For large engines the pistons have to be cooled, and if the engine is vertical any leakage of cooling water—which somewhat readily occurs—will fall into the crank chamber and will interfere with the lubricating oil. For this reason, it has been found necessary to cool the pistons of vertical engines by means of oil, as is done by Messrs. Sulzer. In the case of the horizontal engine, the cooling water cannot mix

up with the lubricating oil, and there is no difficulty therefore in water-cooling the pistons in exactly the same way as is done with horizontal gas engines.

The details of construction just described have special reference to the four-stroke engine; many of them, however, apply also to the two-stroke engine without alteration, such as the fuel valve and the air-compressor, the framing, crank shaft and connecting-rod. Others, such as the cam shaft and cylinders, are modified, and in order to scavenge the exhaust and introduce pure air into the cylinder at the bottom of the stroke, as already mentioned, an air blower or compressor, capable of giving a pressure of from 4 lbs. to 8 lbs. per square inch, has to be provided in addition. As regards removal of the exhaust, two systems are adopted. In one of these, as adopted for smaller engines by Messrs. Sulzer and by Messrs. Carels, scavenging valves are placed in the cylinder cover, which are similar in construction to the exhaust valves. In the larger engines and in the marine engines, however, the scavenging valves are placed at the bottom of the cylinder; they are also placed in the air pipe, and then are made as piston valves.

In the other arrangement adopted, for example, by the Maschinenfabrik Augsburg-Nürnberg Co., ports are cut in the cylinder which are uncovered by the piston at the bottom of the stroke. The air enters the cylinder by the ports on one side, and the exhaust is expelled at the other side of the cylinder, as is done in many two-stroke petrol engines—for example, the Day engine. Figs. 25 and 26 show the two arrangements above described.

The air blast is also obtained in two different ways, (1) by a separate blower, and (2) by enlarging the piston at the bottom to form an air-compressing cylinder placed under the combustion cylinders. These arrangements are illustrated in Figs. 40 and 26 respectively. (At the lecture Fig. 26 was illustrated by means of a working model lent by Messrs. Babcock and Willcox, Ltd.) Messrs. Carels use a double-acting pump driven by levers off the cross-head, following the marine practice of driving the air pump. Messrs. Sulzer use an air-compressor driven by an eccentric from the crank shaft. Another arrangement is to have separate vertical compressing cylinders driven direct by the crank shaft, and in the marine Maschinenfabrik Augsburg Nürnberg Co. engines, for the two-stroke single-acting engine a large trunk piston arrangement is used, while for the two-stroke double-acting engine they use a separate blower.

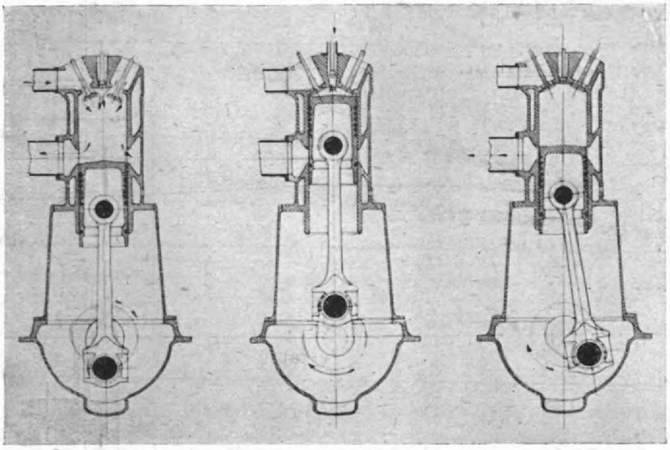

FIG. 25.

The scantlings of the two-stroke engine are substantially the same as those of the four-stroke engine of the same cylinder diameter, but it must be remembered that nearly double the power is obtained. The turning effort is better, as will be obvious from Fig. 14, and therefore a smaller fly-wheel can be used to obtain the same degree of regularity; the fuel consumption per B.H.P. is, however, somewhat higher owing to the extra work required for the air scavenging, and the stroke of the engine has to be made about 10 per cent. longer, to allow for the idle portion of the travel while covering or uncovering the lower exhaust ports. The initial cost is stated by Dr. Diesel to be about 20 per cent. less than that of the four-stroke cycle.

Four cubic feet of free air compressed to

Hosted by Google

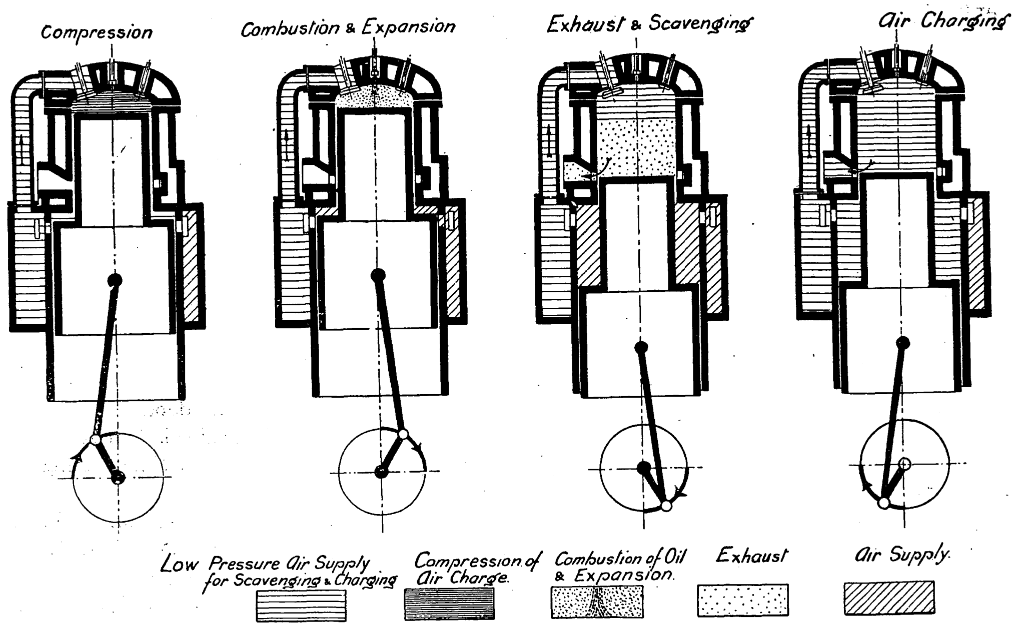

DIAGRAM DESCRIPTIVE OF WORKING TWO-CYCLE ENGINE.

FIG. 26.

from 4lbs. to 8lbs. per square inch is an ample allowance per B.H.P. per minute. Thus, in the case of two 5,000 B.H.P. engines, 40,000 cubic feet of free air would be required to be compressed per minute to about 5 lbs., and this would probably be most effectively done by means of a turbo-blower.

Another estimate is that one hundred cubic feet of air at 2½ lbs. per square inch are required per second for a 2,500 I.H.P. engine, which is equivalent to 2·8 cubic feet of free air per B.H.P. per minute. The volume swept by the scavenging air pump should be considerably greater than that swept by the engine piston, say, 1·8 times.

For marine work it is desirable to have two scavenging pumps; one as a stand-by.

Marine Diesel Engine.

Up to the present single-acting engines have been considered; but either the four-stroke or the two-stroke type can be arranged to work double-acting. In this case the ordinary box piston has to be used, together with a piston rod and its gland. The piston rod has to be of large diameter owing to the stresses to be resisted, and, owing to the high temperatures to which they are exposed, considerable difficulties have arisen with the piston glands.

For marine work a special type of Diesel engine has been developed, because, in the first place, a reversing engine is needed, and, secondly, space and weight are of extreme importance. This last requirement has, of course, a greater importance in the case of destroyers, submarines, and such like, than for tramp steamers. Thirdly, fly-wheels are objectionable, and ready starting and stopping are essential.

Dr. Diesel says: "It can now be stated with certainty that the marine engine of the future is to be of the double-acting two-stroke cycle type."

In a recent design of the Maschinenfabrik Augsburg-Nürnberg Co. marine engine of the single-acting type, a piston rod without gland has been connected to a cross-head working on the ordinary guides as in a marine engine. The piston rod is not rigidly fixed to the piston, but is connected thereto by means of a pin. This gives freedom to the piston and prevents any cross stresses.

The reversing of marine engines was originally effected either by means of clutches or else electrically. Later, arrangements were adopted for altering the timing of the valves, but in the four-stroke cycle the solution is somewhat complicated; for example, in the "Selandia" the two-to-one shaft is lifted bodily and displaced longitudinally so as to bring another set of cams into operation, then on stopping and restarting the engine runs in the opposite direction.

With the two-stroke cycle the solution is

Hosted by Google

extremely simple, because a shift of 30° is sufficient to alter the lead of the valve from the "ahead" to the "astern" position. This shift is effected in the Maschinenfabrik Augsburg-Nürnberg Co. engine by having a coupling on the vertical shaft with two stops 30° apart; the coupling comes against one stop for the ahead position, and to go astern there is lost motion to the extent of 30° to come up to the other stop. In the Carels engine the vertical driving shaft has spiral wheels, which are revolved by the

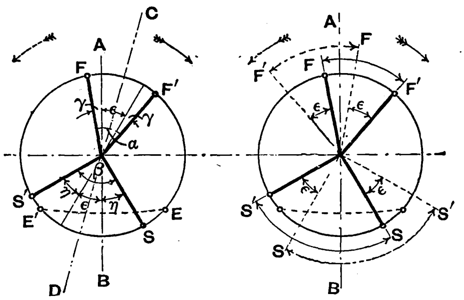

Fig. 27.

starting gear to give the necessary shift o 30°. The reason why a shift of 30° will reverse a two-stroke engine will best be seen by the valve diagram shown in Fig. 27.* On the left-hand diagram, F shows the point of fuel admission, γ being the angle of advance. F' is the point at which the fuel valve closes. S is the point at which the exhaust opens with a lead angle of η, and S' is the point of closing the exhaust. It will be seen that the angle ϵ is equal to the angle between F and F', less twice the angle of advance, and is also equal to the angle between S and S', less twice the angle of lead. Hence, if the timing of all the valves is shifted by the angle ϵ, as indicated by the dotted lines in the right-hand diagram, the opening and closing of the valves will be correctly adjusted for reversing. This angle, ϵ, is about 30°, and the shift is effected as above described.

As regards the general design of marine Diesel engines, according to Mr. Milton only the cylinders should be "Diesel," and the motion and framework should follow exactly present marine practice.

Number of Cylinders.

The number of cylinders to be employed is a somewhat vexed question, and the tendency is to use a great many, and for two reasons—First, unless water-cooled or oil-cooled, 24 ins. seems to be the largest cylinder possible, and from such a cylinder at 200 revolutions per minute the B.H.P. obtainable is 400 on the two-stroke cycle. When the piston is either water- or oil-cooled, much larger cylinders can be employed, and it would appear that 2,000 h.p. per cylinder is then obtainable. Experiments have been made with these large cylinders by the Maschinenfabrik Augsburg-Nürnberg Co., and by Messrs. Sulzer, and, so far, have been satisafctory; but no doubt some time must yet elapse before it can be said with certainty that the present arrangements are really practically satisfactory. The second reason is that many cylinders are needed to obtain a uniform turning moment, depending again, however, on whether the engine is four-stroke or two-stroke, and whether it is single-acting or double-acting.

For land work, so far, moderate sizes are being used and large fly-wheels are not objectionable, and are in some cases necessary to cope with the external changes of load. Sometimes the rotor of a dynamo supplies a large portion of the fly-wheel effect. Four lines appears to be the maximum used; three lines are very common, and for smaller sets two lines and even one are suitable.

For marine engines, however, fly-wheels are objectionable for manœuvring and reversing reasons, and as a rule the engines are of larger power, and hence six lines, and even eight lines are common.

Except for horizontal engines tandem cylinders are not used.

(*To be continued.*)

AN ARTESIAN TUBE WELL.

The authorities of the Institution of Civil Engineers having come to the decision of providing an independent supply of pure water from an artesian tube well to meet the requirements of their new building in Great George Street, Westminster, boring operations were commenced from the sub-basement floor of the building, 19 ft. below street level.

Beginning with 10-in. outer protecting tubes reaching through the gravel well into the solid clay so as effectually to seal out all sub-soil water, tubes of a smaller size were next employed telescopically for the temporary lining of the intervening strata from the clay to the chalk to enable the permanent tier of 6-in. tubes to be carried to the chalk, into which they were tightly driven 18 ft., thus effectually sealing out the very fine Thanet sand, which otherwise might interfere with the proper working of the pump.

This accomplished, the borehole was continued unlined a further 210 ft., thus making a penetration

* Reproduced by kind permission of the *Engineer*.

Hosted by Google

of 228 ft. into the upper chalk formation, or a total depth of 450 ft. from basement floor.

When the chalk springs were struck the water rose to within 174 ft. of the basement, *i.e.*, to 176 ft. below ordnance datum. An exhaustive pumping trial on the completion of the boring demonstrated that the well was capable of yielding quite double the quantity required for the needs of the establishment, and it may be mentioned that the whole work was completed in the very short space of seven weeks.

A feature of interest is the fact that the water, though drawn directly from the fissures in the chalk, is yet very soft, this being accounted for by the chalk being hydrostatically in communication with the overlying Thanet sand bed, the water from which is of an alkaline nature, whereas in other districts in the London Basin where the Thanet sands are missing, chalk water is naturally of a more or less decidedly hard nature.

The thicknesses of the different formations of strata passed through may roughly be given as follows: alluvium, 17 ft. 6 ins.; tertiaries (consisting of London clay, 118 ft. 6 ins.; Woolwich and Reading beds, 58 ft.; Thanet sand, 28 ft.); and upper chalk, 228 ft.

THE MUSEUM, THE SCHOOL, AND NATURE-STUDY TEACHING.*

Museum officials have at last realised the necessity of studying the needs of the visitors to the collections under their charge. The search for knowledge through the impetus given by free education has made museums, along with similar institutions, centres for research. Hence the museum must have its ideal, and a definite plan for carrying it out has to be evolved. Into this scheme educational types of exhibits must necessarily come. The public has to be divided into classes, and exhibits must be suited to each. Hence the material, since it is specialised, is much more valuable than any other former methods could devise. One section, the students' section, is increasingly useful, and therefore requires special development.

Moreover, it is obvious that the museum is merely part of a general scheme of education that each child in its educational progress may—or should—make use of, in the same way as an art or technical school, free library, and so on. Hitherto, however, this fact has been lost sight of, and it is to emphasise the importance and to demonstrate the practical value of the museum in the education of the young that this summary is devoted. A parallel feature of modern education has been the rise of Nature-study. Evolved from the old object-lessons, it has now emerged as an experimental subject into the clear light of advanced methods. It is in fact a method, teaching observation, inculcating logic and reasoning power—and no age was more in need of this—instilling a desire to learn in the young mind, and communicating enthusiasm.

This being so, it is a subject to encourage. The value of Nature-study lies in its association with things, and the necessity of handling them. But it is the museum, above all, which deals primarily with concrete examples, where a man can illustrate ideas by specimens, which he may even touch. Indeed, for the student a museum is the only place in the district where—in Natural Science at any rate—a knowledge of types of different things can be seen and studied. Hence its importance for use by schools.

Within the last ten years museums have been much visited by schools. But it is unfortunate that the true inter-connection between the two has been ignored, and the museum has not been used to advantage. There has been no co-operation. Teachers have used museums in their way without inquiry. Recently, however, realising the necessity of ensuring the effective use of Leicester Museum, lectures have been delivered to the elementary school teachers upon the material in the museum, and upon the general principles of scientific subjects, with considerable success. The extension of this system is advocated.

* Abstract of paper read before the Educational Science Section of the British Association by A. R. Horwood.

EXPERIMENTS ON "SUCTION" OR INTERACTION BETWEEN PASSING VESSELS.*

In view of the general lack of experimental data as to the magnitude of the mutual forces involved in the cases of interaction between two vessels moving in parallel paths in close proximity, and as to their effective range of action, the authors decided to carry out a series of experiments to investigate these points on boats of sufficiently large size to enable the results to be applied with some confidence to seagoing vessels. The vessels used were the steam-yacht "Princess Louise" and a motor-boat. Each is propelled by a single screw, and their details are given in the table below:—

* Abstract of paper read before the Engineering Section of the British Association by Professor A. H. Gibson, D.Sc., and J. Haunay Thompson, M.Sc., M.Inst.C.E.

Vessel.	Length between perpendiculars.	Beam.	Draught.	Displacement.	Rudder Area.
	Ft. In.	Ft. In.			
"Princess Louise"	88 6	13 0	6 ft. forward 7 ft. aft	—	—
Motor-boat	29 6	6 9	2 ft. 3 in.		100 sq. in.

Hosted by Google

Two sets of experiments were carried out. In the first the helm of the motor-boat was lashed amidships, with the vessels on parallel paths, and its behaviour was noted when at different lateral distances, and when the boats were moving at different absolute and relative speeds. Its position relative to the "Princess Louise" was determined by angular measurements taken from the latter vessel at intervals of fifteen seconds. Pressures at a series of corresponding points on the two sides of the motor-boat were measured at the same instants, with a view to determining the lateral forces involved.

The second series of experiments was devoted to a determination of the helm angle necessary to maintain the course of the motor-boat when in different positions relative to the larger vessel.

Owing to possible collision risks the maximum speed was limited to six knots, which, in the case of the "Princess Louise," corresponds to eighteen knots in a vessel of the size of the "Olympic." The results show that with both vessels moving at about this speed with helms amidships the smaller vessel is drawn into collision from any lateral distance less than a hundred feet (three and a half lengths of the smaller vessel). The precise behaviour depends largely on the relative and absolute speeds of the vessels and on their initial distance apart and initial relative position. These points were discussed in the paper, as was the question of the helm angle required to prevent collision.

The authors are of opinion that the experiments prove conclusively that the forces involved during interaction are much greater than has been generally realised hitherto, while they have been particularly impressed by the rapidity with which collision usually follows the first sign of any interaction.

LIFE-BOATS ON OCEAN-GOING SHIPS AND THEIR MANIPULATION.*

The urgent necessity for revising present regulations referring to life-saving appliances at sea has recently been brought home with terrible force to the public mind. Anticipating the ultimate results of the international deliberations at present in progress, the United States Government have already stipulated that every ocean-going passenger steamer must provide sufficient boat accommodation for every soul on board.

To the lay mind such a rule must appear perfectly reasonable, seeing that no objection on the ground of expense can be permissible in a matter of this nature. But it must be borne in mind that the mere fact of carrying a full complement of life-boats implies no guarantee of safety. Unless the boats can be readily manned and launched with a fair degree of certainty, they only constitute so much lumber usually carried about. And it may be categorically stated that there are a large number of ships now in commission on which boats cannot be efficiently arranged to accommodate everybody on board.

Considerable improvement may, however, be effected in the conditions hitherto prevailing, and it may safely be said that all the better-class passenger-carrying companies are giving the matter most careful attention. The general adoption of wireless communication between ships, and also the success of anti-rolling tanks, have enormously augmented the value of the life-boats in cases of emergency. The last-mentioned invention practically removes the risk of boats getting crushed against the side of the ship when lowered in bad weather, and wireless telegraphy has reduced the question to one of providing means for transferring people from one ship to another in case of disaster. Strong seaworthy boats, with the largest obtainable displacement for a given length, will now best meet the requirements, a high degree of navigability being of much less importance than formerly. Detachable deck-houses, life-rafts, and the like, are, in the author's opinion, of very limited value.

On account of the continually increasing height of modern ships, the old question of substituting wire ropes for the usual manila falls has come up again with renewed force. The problem is, however, one of considerable difficulty in view of the ever-varying conditions under which the launching of the boats may have to be carried out.

The first ship to obtain a really efficient davit installation of this nature is the steamship "Imperator," of the Hamburg-Amerika Line, on which the majority of the boats stand some seventy feet above the water-line. The launching of boats on this vessel may be effected in from forty to fifty seconds, and a special adjusting gear permits of the boat descending at any required angle—a point of the greatest importance. The hoisting is done by means of an electrically-driven "fore-and-aft" transmission shaft provided with "friction-drivers," each boat being handled quite independently of the others. The largest life-boats are capable of accommodating seventy-six people, and weigh, fully loaded, approximately eight tons each.

* Abstract of paper read before the Engineering Section of the British Association by Axel Welin.

EMPIRE NOTES.

Colonial Representative Government.—The rapid and solid growth of Canada was brought home to all who were able to attend the recent celebrations at Halifax, Nova Scotia, when the beginnings of representative government were commemorated by the inauguration, by H.R.H. the Duke of Connaught, of a national memorial tower. When John Cabot discovered Cape Breton, neither he nor his contemporaries had any idea of what that discovery meant, any more than we to-day can foresee the ultimate magnitude of the Canadian Dominion. This year is the 154th anniversary of the opening of the Nova Scotian Assembly, and it

Hosted by Google

is claimed that this is the earliest legislative body to be set up in the present Colonial Empire. This claim, however, may be contested by Bermuda and Barbadoes. Mr. Algernon E. Aspinall, in writing to the *Times*, points out that Bermuda was granted representative government in 1620, and that Barbadoes had representative institutions granted to her by Royal Charter in 1627, and confirmed by the Commonwealth in 1652. The dedication of the memorial tower in Halifax, and the event commemorated are of outstanding importance in the history of our Imperial race. When we look back 154 years to October 2nd, 1758, and at the nineteen representatives elected by the people of Nova Scotia, who formed the first legislature, we realise that that assembly, although perhaps not marking the beginning of the policy of self-government within our Empire, is yet one of the first great steps in that direction. The advisability of noting that event for the present and future generations is apparent. Since the germ of representative government was planted in Halifax, the British Empire has taken root in Australia, New Zealand, India, and the Cape. Nine provincial and one federal legislatures have been developed in the Dominion Government alone, and some thirty or thirty-five others throughout the Empire. The humble gathering of the nineteen representatives of the early settlers of Nova Scotia may lack the brilliance and the glory of the battle of Plassy of the previous year, or the Plains of Abraham of the following year, but in it is assuredly the foundation-stone of the Empire's greatness and development—the principle of self-government.

Motor-cars in Canada.—It is interesting to note how the well-being of Canada is shown in the common use of the motor-car, and this despite the hindrances in the way of poor roads and other obstacles to locomotion. The bulk of the cars are imported, the greater number from the United States, and a few from England. There are, however, seven or eight motor companies in Canada, two of which are native Canadian undertakings turning out a special type of car. The popularity of the car is greater in western than in eastern Canada; and this is easily explained by the contrast between the topography of these two parts—the open prairie, with its trail and small rainfall, permitting easy travel in almost every direction. Doubtless, if the tests now being made in Australia of the motor-car, which is made on very much the same principle as the stump-jump plough, and rides over rough bush roads without jolting. passengers or goods, are successful, the eastern provinces of Canada will be able to make use of motor locomotion in many districts where it is now practically impossible.

The Australian Trans-continental Railway.—The ceremony of turning the first sod of the great Australian railway which will link up east and west was recently performed by the Governor-General. With the construction of this railway, 1,073 miles in length, the federation of Australia will be completed in a manner which no common constitution or common laws could effect. One of the prime objects of the railway is to provide for more efficient defence by enabling troops to be transported quickly from east to west, should any of the ports of Western Australia be attacked. It is to be hoped that its usefulness as an adjunct to civilisation will have justified its building years before the test of defensive necessity arises, if it ever does. Although war is to be deprecated, the fear of attack will be of service to Australia if it spurs her on to develop her immigration policy, and to build such railways as those which will soon traverse the continent from east to west and north to south, thus rendering available her vast unutilised resources. Much of the railway from Port Augusta to Kalgoorlie lies in country of very low rainfall, which has hitherto been regarded as desert. But everywhere in Australia the desert has steadily shrunk before the march of knowledge and settlement. There are flourishing sheep and cattle stations now near Cooper's Creek, in Queensland, where Burke and Wills starved to death in their memorable exploring expedition fifty years ago. It is therefore permissible to hope that when the railway is built very much of the land bordering upon it will be found useful for pastoral settlement, if not for agriculture. The surveys, indeed, have already proved that this is probable. The storage of water obtained from the rainfall is possible in several places, and artesian wells will, doubtless, become the centres of flourishing oases where crops and fruit will be grown. There is also more than a probability that the building of the railway will lead to the discovery of new deposits of metals and minerals, and the building of busy towns in the wilderness. It may be several years before the railway begins to pay in the monetary sense, as eventually it is sure to do, but in the meantime it more than justifies itself by bringing west and east into closer relations, and rendering complete the federation of Australia.

Southern Rhodesia.—The report for 1911 of the Director of Agriculture for Southern Rhodesia can now be obtained, and shows the rapid strides which husbandry is making in that colony. The total area under cultivation is about one million acres, the increase in all European crops since last census being very considerable. Thus maize shows a 758 per cent. extension, tobacco has risen from 147,000 lbs. in 1904 to 606,000 in 1911, and coffee from 42 lbs. to 14,000 lbs. The report speaks of a steady rise in the leading exports—hides, skins, tobacco, maize, and onions—and of substantial purchase of agricultural machinery. The ranching industry has also made satisfactory progress, the Leibig Company alone having introduced over 1,000 head of cattle. Similar ventures on a smaller scale are coming into being in various parts of the country. The culture of tobacco in Rhodesia, although already a large and flourishing industry,

Hosted by Google

is really only in its infancy. It is the rich, low-lying portions of Rhodesia which, as railway communication is opened up with the markets, will furnish double, and even treble, crops with a minimum of trouble. Down on the low veldt, in the great sandstone belts that traverse the country from Wankies to Lomagundi, are valleys where tobacco can be grown under ideal conditions; and eventually, as settlement proceeds, the low veldt will be tapped by one or more railways. When that occurs the industry should make giant strides.

Egyptian Oil.—There is much interesting reading in the account of the exploration work that has been done in the Egyptian oilfields, and which is being pushed forward with energy. The one area which appears to have proved to be productive on a commercial scale is that comprising the peninsula of Jemsa, the oil yield there being mostly of good quality and the barrellage satisfactory. Evidence of oil is also to be found on some of the islands as well as on the mainland. Prospecting is being carried still further afield, and it is probable that at an early date sinking will be undertaken in other areas than those already being carefully explored. There has been active development of other mineral products quite recently. Two companies are prospecting large occurrences of manganese ores on the western side of the Sinai Peninsula to the north of Tor, and a large deposit of phosphate ore is now being worked on the western coast of the Red Sea.

NOTES ON BOOKS.

Colour in the Home. With Notes on Architecture, Sculpture, Painting, and upon Decoration and Good Taste. By Edward J. Duveen. London: George Allen & Co., Ltd. £2 2*s.* net

"Magnifica in Frontispicio, Ridicula in Penetrali," is found, on reading through this sumptuous volume, in no way to apply to it, notwithstanding that the disproportion between its size, and whole "format," might well suggest to an incautious critic that it was but another of those Buncombe books of "three-colours printed" illustrations, all binding and pulpy paper, wherewith—since George Cruikshank, and Richard Doyle, and Randolph Caldecott, and Kate Greenaway have ceased to live for us—our publishers have, during the past three or four years, been piling up their counters throughout Christmas tide. This volume is 12½ inches in height, and 10½ in breadth, and 1¾ in thickness; and although it contains but seventy-five pages of actual text, it weighs 4 lbs. 11 ozs.; this weight including that of forty-four or forty-five illustrations, with their added "label-sheets," and of course the binding; which, for all its chaste harmony of French grey and gold, is not strongly "forwarded." The illustrations in not a single instance justify paper of such imposing dimensions, while to trickle a text of about 300 words through "meadows of margin" 2¼ inches and 2½ inches, top and bottom, respectively, and 2¼ inches on the outer side, and 1¼ on the inner, is indeed "wasteful and ridiculous excess" in the art and craft of "book-making." I am the more extreme to mark these details, not so much because of the growing tendency observable of recent years to subordinate the art to the craft of costly publications, as because the bad taste of it always arouses suspicions of their good faith; than which nothing can be more damaging in the case of books dealing with the fine arts, and the applied arts, and education in art. Mr. Duveen's book should have been a crown 8vo, bound in French grey and gold, as it is, but stronger backed; and to range on the shelves with such classical monographs as Yates' "Textrinum Antiquorum," Thomas ["Anatasius"] Hope's "Household Furniture," and John Burnet's "Treatise on Painting."

But this remonstrance put aside, and turning to Mr. Duveen's personal part in the production of the volume, he may rest assured of the gratitude and praise of every cultivated reader for a most instructive and captivating essay on "Colour in the Home," based on the soundest technical, and scientific, and philosophical inductions, and expressed in the simplest terms, and illustrated with the happiest and most effective pertinence by a man of unfailing good taste in all his chromatic combinations,—painting from a Florentine palette delicate and dainty as Botticelli's own. Every paragraph, every picture throughout the essay, is set in "the quiet and still air of delightful studies," and, its unhandiness notwithstanding, it provides the right inspiration for all persons of ample means and refinement, who would have their homes made beautiful. For all the lucidity and ease of Mr. Duveen's literary style, it is evident that he has studied his subject in the writings of its greatest theoretical and practical exponents, from Plato to Goethe, and Hegel, and Schopenhauer, and from Aristotle, and Ptolemy, to Newton, and Helmholtz, and Chevreul; and, being endowed with innate good taste of his own, perfected by practice, his essay may also be unreservedly recommended as a working "Vade Mecum" to all experts in art professionally occupied in its application to the construction, furnishing, and decoration of "the stately homes" of the wiser of the wealthier classes of the United Kingdom. I repeat the qualifications,—"of the wealthier classes," and "persons of ample means," because true artistry demands that the houses of the merely comfortable middle classes, and, again, of the cruelly competitive wage-earning labouring classes, should not be, literally, tricked out with worthless and vulgarised imitations of the chairs, tables, bedsteads, and upholsteries, and other chattels, of the hereditary, and the newly enriched, or "jumped up" upper classes.

Hosted by Google

A novel and most suggestive feature of Mr. Duveen's essay is to be found in the chromo-prints interleaved with it, in illustration of schemes of decoration for dwelling-rooms, based on the colourings of the wings of butterflies and moths. The frontispiece, entitled "A Morning Room," and, again, a print toward the end of the volume, entitled "An Elizabethan Oak-panelled Dining Room," are most fascinating examples of this, so far as I am aware, entirely original device for applying chromatic harmonies adapted from the wings of insects to the purposes of art furniture and general household decoration. There is, indeed, no problem arising out of the contemplated decoration of our dwellings, whether of proportion or colour combinations, that Mr. Duveen's monograph will not help those who consult it to solve; provided always that they themselves have an eye for just proportion, and for concordant colouring, alike in its diffusion and focal centres. What Mr. Duveen says on the mental and moral effects of colours, on pages 73, 74, I must quote in full:—"In all harmonious combinations of colours, whether of mixture or neighbourhood . . . (blue) is in colouring what the note C is in music, the natural key archeus or ruling tone. Universally agreeable to the eye, when in due relation to a composition, it may be more frequently repeated therein in its purest or unbroken state, than either of the other primaries [yellow and red]. The moral expression of effects of blue or its influence on the feelings and passions partake of its cold and shadowy relations in soothing and inclining to melancholy [cf. 'the blues'], accordingly it is rather a sedate than a gay colour, even when in its utmost brilliancy. These analogies and effects of colour are by no means to be disregarded; they have a stronger influence on the mind than they are generally credited with, and it is by attention to them that colour conduces to sentiment and expression in painting. Even when the symbolical uses of colour are merely fanciful or conventional, they are not to be neglected, since by association and common consent they acquire arbitrary significance. With white and all colours that approach it, we associate gladness and gaiety, while sorrow and pain, and mystery, immediately arise in the imagination with blacks and solemn browns. These feelings are inherent and in the nature of things, and just knowledge of the relations of colours and their effects upon the passions and feelings seem hardly less essential to the poet than to the painter; hence he often employs their ideas and terms with happy effect."

This is sound in science, and philosophy, and tradition, and technique, and could not be more soberly and lucidly put; and the truth of it all should ever be present to the mind of the architect, the decorator, and the house furnisher, and particularly of the upholsterer. Mr. Duveen has also some very pertinent observations on the dressing of women; but this is not so vital a matter, for, in fact, so long as a woman is either ladylike, or good-hearted, or merely good-looking, whatever her "wear," it will become herself—even the current execrable fashions of women's "wear," that violate every canon of art, and, in the case of vulgar women, of propriety; and therefore I will refer readers of our *Journal*, interested in this entirely æsthetical problem, to Mr. Duveen's monograph itself. He will fully repay them as a guide in colour; for form, they should go to the afore named Thomas Hope, his "Costume of the Ancients," and "Designs of Modern Costumes," both written over a hundred years ago now: but—"What is best is ever fresht."

GEORGE BIRDWOOD.

THE POSITION OF LANDSCAPE IN ART. By "Cosmos." London: George Allen & Co., Ltd. 3*s*. 6*d*. net.

Whether they agree or not with the principles and conclusions laid down by "Cosmos," readers of this volume will find it both readable and stimulating. It has apparently been provoked, in part at least, by recent developments in the world of art. "Cosmos" has no patience with impressionists, post-impressionists, cubists, futurists, *et hoc genus omne;* he has only a lukewarm appreciation even of Whistler; but on the other hand he has a very great and well-reasoned admiration for those who are generally recognised as the great masters of painting. With this part of his thesis probably the large majority of his readers will be in cordial agreement; but when he comes to consider the position of landscape in art, no doubt he will find a good many disposed to question his views. Landscape painting, he thinks, has been placed on a pedestal far higher than its merits deserve; and he blames Ruskin for having brought about this state of things, with its deplorable consequences—"thousands of landscapes, good, bad, and indifferent, which form the flotsam of the art trade . . . and the unrecorded history of useless industry and wasted lives, of broken spirits and despairing hearts." There can be no doubt, of course, that we have an enormous superfluity of bad and indifferent landscapes, but would a similar superfluity of bad and indifferent figure pictures be any better? Possibly, however, the contention of "Cosmos" is that Ruskin encouraged a large number of people, who ought never have tried to hold a brush at all, to become painters of landscape, and if this is his point far be it from us to dispute it, for neither men, gods, nor the picture dealers ought to permit mediocrity in painters any more than in poets. We are, however, still disinclined to admit the comparatively lowly function which he would ascribe to landscape painting. We have known people who have drawn a more complete and satisfying pleasure from the calm beauty of Rembrandt's "Mill" than from all the sacred masterpieces which "Cosmos" would set high above it.

"Cosmos" is perhaps at his best when criticising the critics. In Chapter VII. he deals excellently with the champions of the post-impressionists, and

Hosted by Google

reduces their premises to their logical absurdity. But it is not only post-impressionist critics who write the sort of stuff that the uninitiated can only describe as bunkum, and in one of his notes at the end of the volume, "Cosmos" quotes some gems from the pen of one who is regarded by many as a high authority. Speaking of a portrait by Rembrandt in the last Winter Exhibition of the Royal Academy, this critic writes: "Nothing could be greater or simpler. And by what magic—though we do not leave earth or the commonplaces of everyday existence—is the whole great problem of humanity, of life, thus indefinably evoked? No veil is lifted; yet the wonderment of man at the awful mystery that is his brother-man, the going out in all humility of heart and soul to heart and soul, the fusion by sheer love of one being in another—these things are suddenly realities to us." And again, of Watts's picture, "The Sisters": "There is in the picture, above all, a chord compound of music of two souls, vibrating not in unison, but in a relation subtler still, and more beautiful." Well may "Cosmos" remark that it is amazing to what length English critics sometimes go in their endeavours to find psychological meanings in pictures.

GENERAL NOTES.

Celluloid.—In view of the recent disastrous fires which have occurred in places where celluloid is stored, it is interesting to learn that the Home Secretary has appointed a committee "to inquire and report as to the precautions necessary in the use of celluloid in manufacture, and the handling and storage of celluloid and celluloid articles." The names of the members of the committee are: The Earl of Plymouth (Chairman); Professor James J. Dobbie, F.R.S., Principal Government Chemist; Captain Maurice B. Lloyd; Mr. H. M. Robinson, Deputy Chief Inspector of Factories; and Mr. Edwin O. Sachs, Chairman of the Executive of the British Fire Prevention Committee.

The "Shipbuilder."—After six years' existence as a quarterly, the *Shipbuilder* has, with the October number, been converted into a monthly journal. It will continue to be published simultaneously, as heretofore, in London and Newcastle-on-Tyne, and will be exclusively devoted to shipbuilding, ship repairing, and marine engineering.

"The International Whitaker."—Messrs. J. Whitaker & Sons, Ltd., are preparing an international edition of their almanack under the title of "The International Whitaker." The new book, which supplements but does not supersede the older "Whitaker," is to be bound in cloth and to contain about 700 pages. The armies and navies of the Great Powers, the trade of the leading mercantile nations, and the needs and possibilities of partially developed countries are receiving special attention. The volume will be published early in December at the net price of 2s.

The Java Tea Industry.—The cultivation of tea was introduced into the island of Java in 1826, and was classed among government cultures. About 1842, private planters in the island began to occupy themselves with this culture, which until then had been monopolised by the government. After the Agrarian Bill of 1870 had passed into law, the number of tea-planting companies in Java increased very rapidly. In 1878 Assam tea was transplanted to Java as supplying a product more suited to the taste, and giving a better yield. At present the cultivation of this tea has entirely supplanted that of China tea in the island. According to a report recently prepared by the Netherlands Ministry of Agriculture, the quantity of tea produced in Java in 1900 was 6,600 tons; in 1905, 11,228 tons; and in 1911, 22,800 tons. The bulk of these teas is sent to the Amsterdam and London markets. Of late years, and especially in 1911, large quantities have been also dispatched direct from Java to Australia and Russia, and smaller quantities to other countries.

Japanese Coal for Railways in Chili.—A Santiago journal states that coal from Japan is beginning to be largely used on the Chilian railways. It is found to be cheaper than that of Australia. It is hoped eventually to establish a considerable trade in return by exporting nitrates to Japan and so reduce the cost of freight, to the mutual advantage of both countries.

MEETINGS FOR THE ENSUING WEEK.

Tuesday, October 15...Sociological, at the Royal Society of Arts, John-street, Adelphi, W.C., 8.15 p.m. Professor Geddes, "Mythology and Life: an Interpretation of Olympus."

Photographic, 35, Russell-square, W.C., 8 p.m. Dr. F. Goldberg, "The Resolving Power of Photographic Plates."

Our Dumb Friends' League, Whitehall Rooms, Whitehall-place, S.W., 3 p.m. Mr. J. Buckland, "The Value of Wild-Bird Life in the Empire."

Wednesday, October 16...Microscopical, 8 p.m. Conversazione at King's College, Strand, W.C.

United Service Institution, Whitehall, S.W., 3 p.m. Captain G. S. MacIlwaine, "The Corrugated Ship."

Thursday, October 17...Child Study, 90, Buckingham Palace-road, S.W., 7.30 p.m. Dr. T. Percy Nunn, "Psychological Development of the School Subjects."

Chemical, Burlington House, W., 8.30 p.m. Sir Oliver Lodge will deliver the Becquerel Memorial Lecture.

Automobile Engineers (Birmingham Centre), University Buildings, Edmund-street, Birmingham, 8 p.m. Mr. Douglas Leechman, "The Influence of Low Production Cost on Quality."

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Dr. Francis Ward, "Fur, Fin and Feather under Water." (With cinematograph.)

Hosted by Google

Journal of the Royal Society of Arts.

No. 3,126. VOL. LX.

FRIDAY, OCTOBER 18, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

PROCEEDINGS OF THE SOCIETY.

HOWARD LECTURES.

HEAVY OIL ENGINES.

By Capt. H. Riall Sankey, R.E. (Retired), M.Inst.C.E.

Lecture III.—Delivered May 13th, 1912.

Various Types of Diesel Engines.

There are a very large number of makers of Diesel engines, especially on the Continent of Europe; but so far in this country for land purposes there are only two makers of repute, and the largest engine made by them is about 600 B.H.P. A large majority of the engines manufactured are of the vertical type, and there is a great similarity in all the designs. There is not the same variety that is to be found amongst steam engines, and the reason is twofold; the designs have emanated practically from one source, and the differences caused in steam engines by variations in steam pressure, and whether the engine is condensing or non-condensing, do not occur. The differences consist principally in the methods of driving the cam shaft and the compressor, and in details of valve levers, fuel pumps and governors, as will be seen by an examination of the slides exhibited.

Figs. 28 to 43 are reproductions of some of these slides, and the following is a complete list, together with the special points referred to:—

Experimental engine in 1897 by Messrs. Mirrlees, Watson & Yaryan.

Single-cylinder engine, with vertical compressor driven direct by the shaft, and fitted with large fly-wheel driving a dynamo through flexible coupling. (Messrs. Mirrlees, Bickerton & Day.)

Fig. 28. Similar engine driving a dynamo by means of a belt. (Maschinenfabrik Augsburg-Nürnberg Co.)

Figs. 29 and 29A. 250 B.H.P. two-line engine, A frame design, with ring lubrication. (Messrs. Sulzer Bros.)

Fig. 30. Three-line 450 B.H.P. engine, A frame design, with ring lubrication. (Messrs. Sulzer Bros.)

Three-line engine, closed crank chamber, for forced lubrication.

Fig. 31. Three-line engine driving dynamo direct, fitted with large fly-wheel, A frame with jacket in one casting. Reavell horizontal air-compressor. (Messrs. Willans & Robinson.)

Fig. 32. Two-line engine, A frame type, crank closed in with sheet steel, showing boiler for utilisation of exhaust gases; 8 to 9 per cent. of the total heat is thus recovered. (Messrs. Sulzer Bros.)

Fig. 33. Standard three-cylinder two-stroke engine with exhaust valves in the cover, showing water-cooled exhaust pipes suitable for powers from 600 to 800 B.H.P. (Messrs. Sulzer Bros.)

Fig. 34. Four-line engine driving a dynamo direct, fitted with Reavell compressor. (Messrs. Willans & Robinson.)

Fig. 35. Four-line four-stroke enclosed forced lubrication engine, with horizontal compressor. (Messrs. Sulzer Bros.)

Fig. 36. Standard four-line two-stroke engine, with exhaust belt at middle of cylinder; water-cooled exhaust pipes suitable for powers up to 1,000 I.H.P. (Messrs. Sulzer Bros.)

Fig. 37. Four-line high-speed engine with closed crank chamber for forced lubrication, directly connected to dynamo, suitable for ship work. (Messrs. Sulzer Bros.)

Non-reversing high-speed engine made suitable for ship propulsion by reversing gear. (Messrs. Mirrlees, Bickerton & Day.)

Similar engine showing arrangement of air cylinders and silencer.

120 B.H.P. engine for driving a pinnace, enclosed crank chamber, forced lubrication, friction clutch and reversing gear. Speed can

Hosted by Google

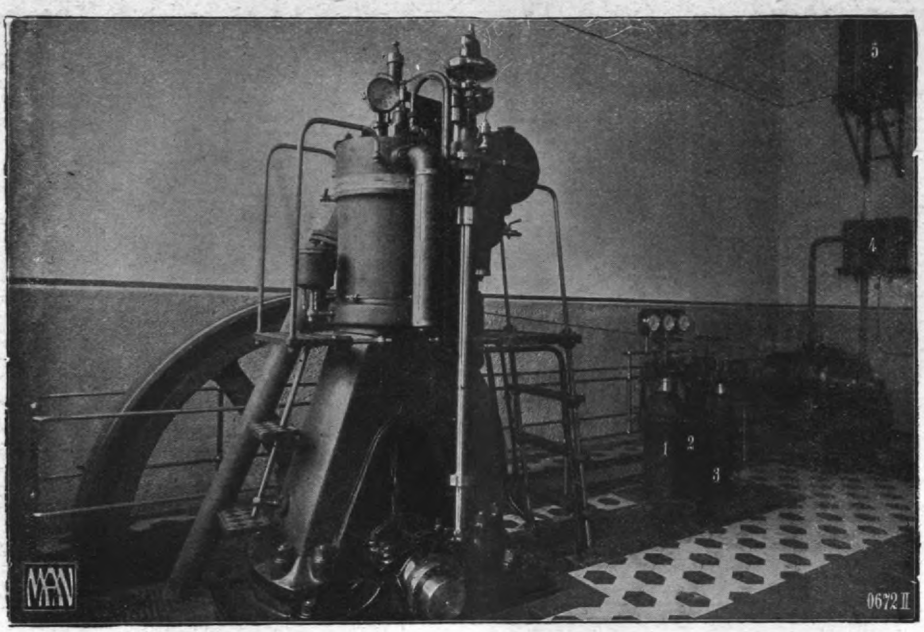

FIG. 28.

be varied over a considerable range; there is a separate compressor driven off the shaft by means of a chain. (Messrs. Mirrlees, Bickerton & Day.)

Three-line double-acting slow-speed marine engine under test. (Maschinenfabrik Augsburg-Nürnberg Co.)

Six-line single-acting two-stroke engine for marine propulsion, scavenging air being obtained by enlargement of the cylinders; two compressors for supplying fuel air blasts, single cam shaft along the tops of the cylinders showing clutch on vertical shaft with 30° play for reversing the engine, hollow connecting-rod, nickel plate for protecting central part of piston against high temperature. (Maschinenfabrik Augsburg-Nürnberg Co.)

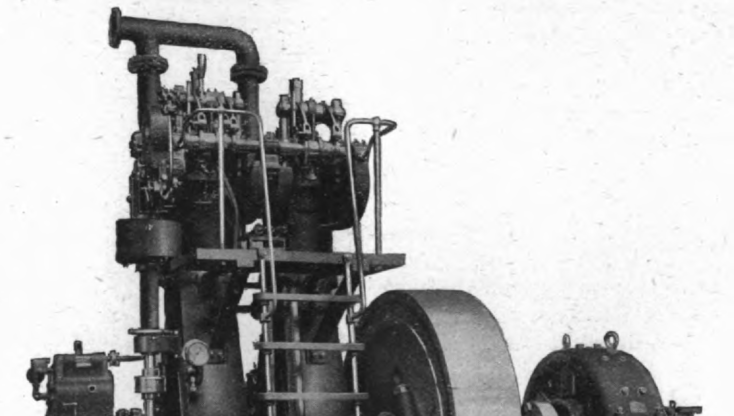

FIG. 29.

Fig. 40. Longitudinal section through engine shown in Fig. 39, showing scavenging blower and two-stage air-compressor driven direct by the crank shaft.

Figs. 41 and 42. Plan and cross-section of the above engine.

Enclosed marine engine, six-line, similar to above. (Messrs. Sulzer.)

Fig. 43. Horizontal double cylinder, single-acting, two-stroke engine of 500 B.H.P., showing scavenging blower, driven direct by extension of crank shaft. (Maschinenfabrik Augsburg-Nürnberg Co.)

SIZES IN CURRENT USE.

Many makers publish lists of sizes up to 1,000 B.H.P. Table II., based on Messrs. Burmeister and Wain's list, gives an example of how, with eleven sizes of cylinders, twenty-four engines can be constructed varying in power from 30 B.H.P. to 1,000 B.H.P., and in speed from 250 revolutions per minute to 150 revolutions per minute. With the A frame form of construction (see Fig. 29) the unit consists not only of the cylinder, but also of the valves, connecting-rod and A frame itself, so that by varying the bed-plate, the shaft and the two-to-one shaft, several different sizes of engines can be built. This is an important advantage from the manufacturing point of view. A similar table (Table III.) has been prepared from the list published by the Maschinenfabrik Augsburg-Nürnberg Co. In this list there are seventeen sizes of cylinders, from which forty-five different sizes of engines are constructed. Only a few of the cylinders are shown in the table to indicate the principle. For each size of cylinder the width and height of the engine is the same, but the length varies according to the number of cylinders. This

table refers to slow-speed engines; for high-speed engines a similar table could be prepared.

Beyond these powers there do not appear to be any standard sizes, but many makers are now prepared to make engines up to 2,000 H.P. and 4,000 H.P. each, and Messrs. Sulzer state that they are prepared to make engines up to 8,000 H.P. running at 105 revolutions per minute. According to Dr. Diesel, the four-stroke cycle engine may at present be regarded as the type for stationary plants from 5 H.P. up to 800 H.P. It is possible, however, that this position may be affected by improvements in the two-stroke engine. For torpedo boats and submarines, a light type of engine has been constructed in which the framing is made of manganese bronze, and such things as doors, etc., of aluminium. The weight of these engines is as low as from 40 lbs. to 54 lbs. per B.H.P., and with six cylinders they give 150 B.H.P. at 550 revolutions per minute. Larger engines with eight cylinders run at 400 revolutions per minute and give 1,200 B.H.P.

High-speed engines are made in two types, heavy and light, the former weighing about 110 lbs. per B.H.P., principally for driving dynamos direct, and the latter weighing from

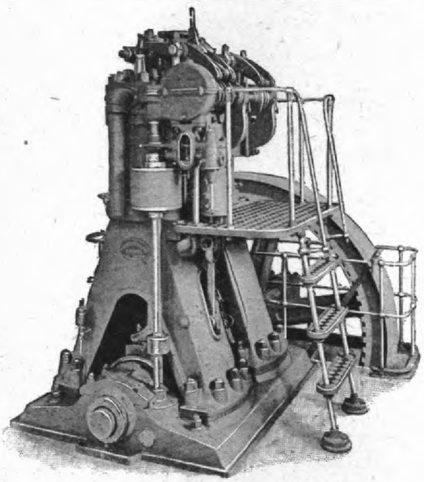

FIG. 29A.

		Heavy.	Light.
150	6	300—400	550
600	6	225—275	450
1,200	8	215	400

FUEL OILS.

The heavy oil engine of the explosion type is much limited in respect of the kind of oil it can use, and great care has to be exercised in its selection. To obtain the best results the compression must be carefully adjusted, and a change in oil usually requires a change in the compression, for which purpose distance pieces are provided for altering the length of the connecting-rod. With the Diesel engine almost any kind of oil can be used, even animal and vegetable; for some of them, however, special arrangements are required, though, generally speaking, no alteration in the compression is needed.

A good deal of confusion exists because some of the oils have different names in the various countries; for example, what we call paraffin oil is called petrol in France, and what we call petrol is called benzine in France. In this country it is not unusual to say that "crude" oil is used with the Diesel engine. "Crude" oil, however, is in reality the natural oil as it comes from the earth, and it contains many oils which are too valuable to burn in a Diesel engine; for example, the benzines and petrols, the illuminating oils, which are also used for the ordinary oil engine, and it is only the residue—known, for example, as "Masut" or "Astaki"—which is generally used in the Diesel engine.

The characteristics of a fuel oil suitable for Diesel engines are the following: chemical composition, viscosity, specific gravity, igniting point, amount of residue, calorific value.

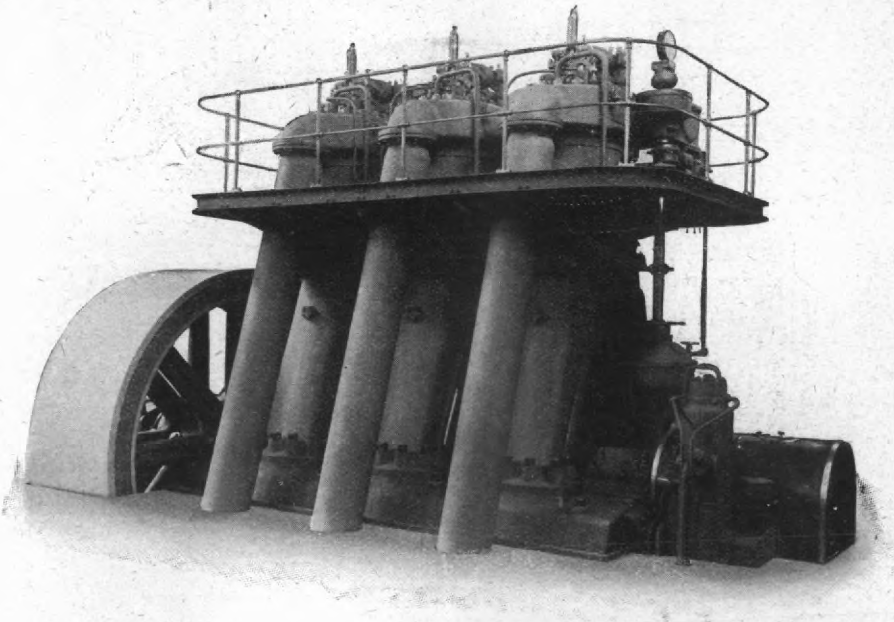

FIG. 33.

Hosted by Google

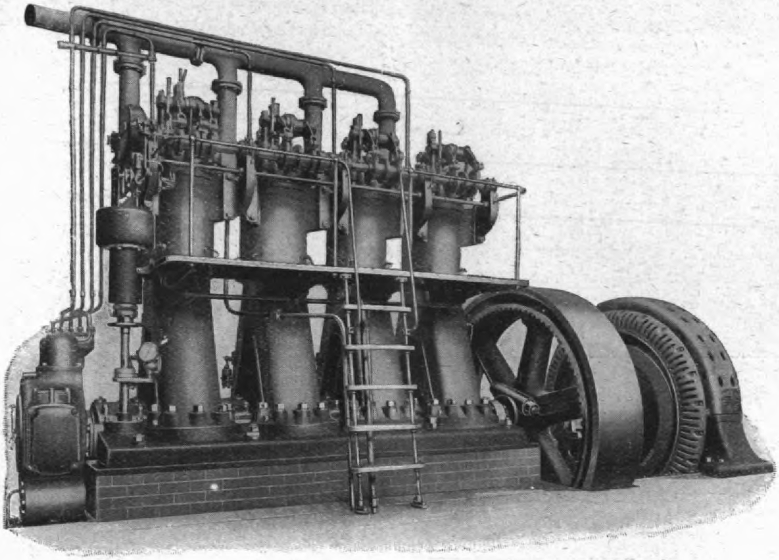

Fig. 34.

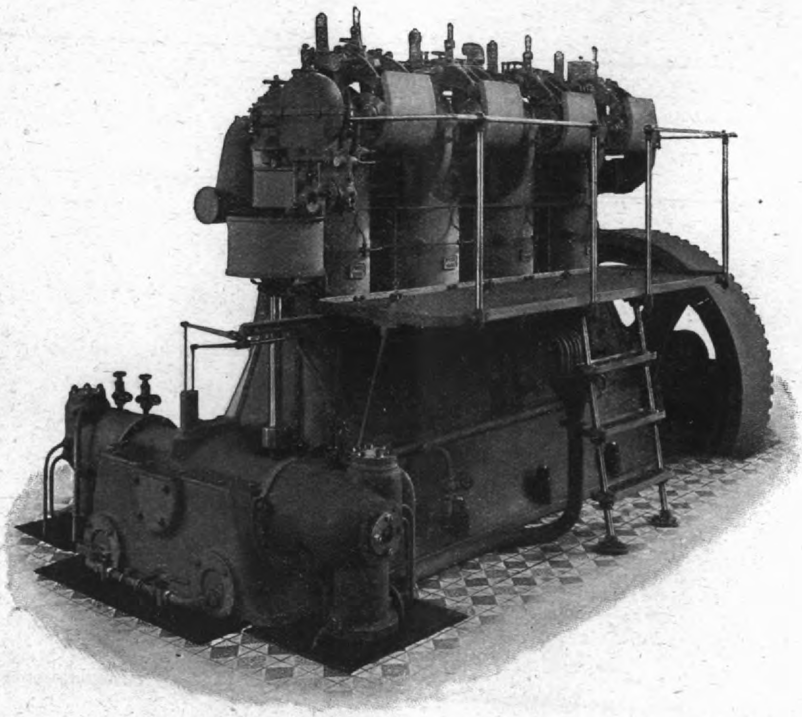

Fig. 35.

Hosted by Google

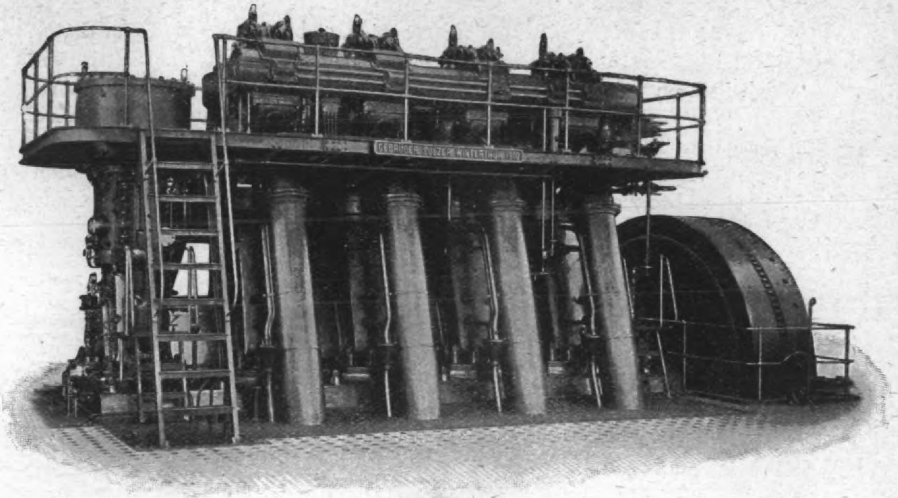

FIG. 36.

As regards chemical composition, these oils being as a rule hydro-carbons consist principally of carbon and hydrogen. In the crude petroleum the proportion by weight of carbon varies from 82 per cent. to 86 per cent., and that of the hydrogen from 11 per cent. to 14 per cent. In the coal-tar oils the proportion of carbon is about 90 per cent., and that of the hydrogen about 8 per cent. The proportion of hydrogen is important, because on it depends the capability of giving off inflammable gas to initiate the ignition even at the high temperature existing in the Diesel engine at the end of compression. If the hydrogen proportion is insufficient, as in the case of coal-tar oils, special ignition oil has to be used to initiate the combustion. Sulphur is an impurity, and must not exceed 1½ per cent.

Viscosity is not of great importance, because if it is high and the oil will not flow readily, it can be reduced to the desired point by warming the oil of the exhaust gases or by adding, say, 5 per cent. of illuminating oil.

The specific gravity is of no consequence *per se*, but is a reliable guide as to the type of oil under consideration. If the flash-point is too low danger may arise in storage, especially on board ship. Lloyd's rule is that the flash-point should not be less than 150° F. The flash-point of heavy oils, however, is over 350° F., and the lower flash-point can only be caused by the admixture of more volatile oils.

If the ignition point is too high, caused, as pointed out above, by insufficient hydrogen, a difficulty will arise with the usually adopted

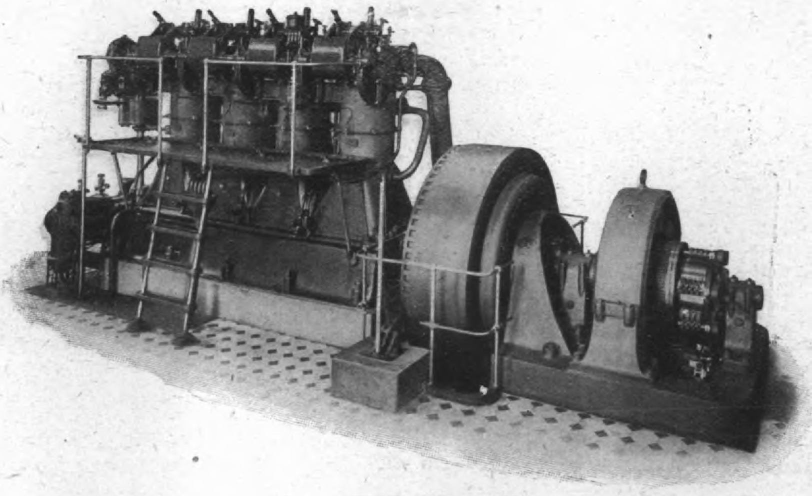

FIG. 37.

compressions of from 450 lbs. to 500 lbs. per square inch. Successful trials have been made with oils having a high ignition point by forcing up the compression to forty atmospheres, that is, about 600 lbs. per square inch; but, practically, the difficulty is got over by the use of igniting oil, which will be referred to more in detail later.

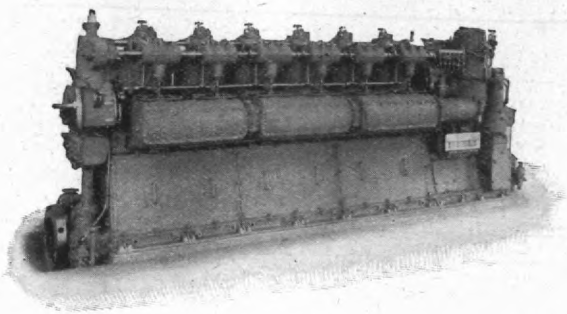

FIG. 38.

The residue should be small, to prevent accumulation on the valves, and so obviate too frequent cleaning of them.

As regards the calorific value, it is important to discriminate between what are known as the higher and lower values, the difference between them being the latent heat of the water produced by the combustion. This latent heat cannot possibly be utilised by an internal combustion engine, or by a steam boiler for that matter, and two committees of the Institution of Civil Engineers, viz., the Committee on Tabulating the Results of Steam Engine and Boiler Trials, and the Committee on Standards of Thermal Efficiency of Internal Combustion Engines, decided that the lower calorific value should be used for all calculations of thermal efficiency. The higher calorific value is that obtained in a bomb calorimeter, and if the proportion of hydrogen is known it is easy to determine the lower value, because the difference between the higher and lower values for hydrogen is 10,305 B.Th.U. per lb., and hence the following rule can be established: Lower calorific value = higher calorific value − 10,305 × H per cent.

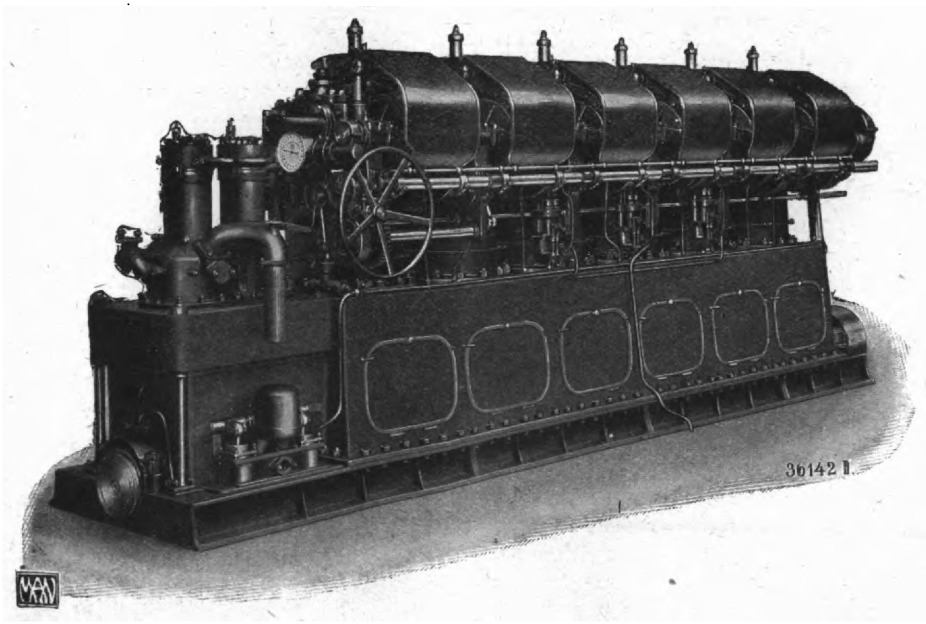

FIG. 39.

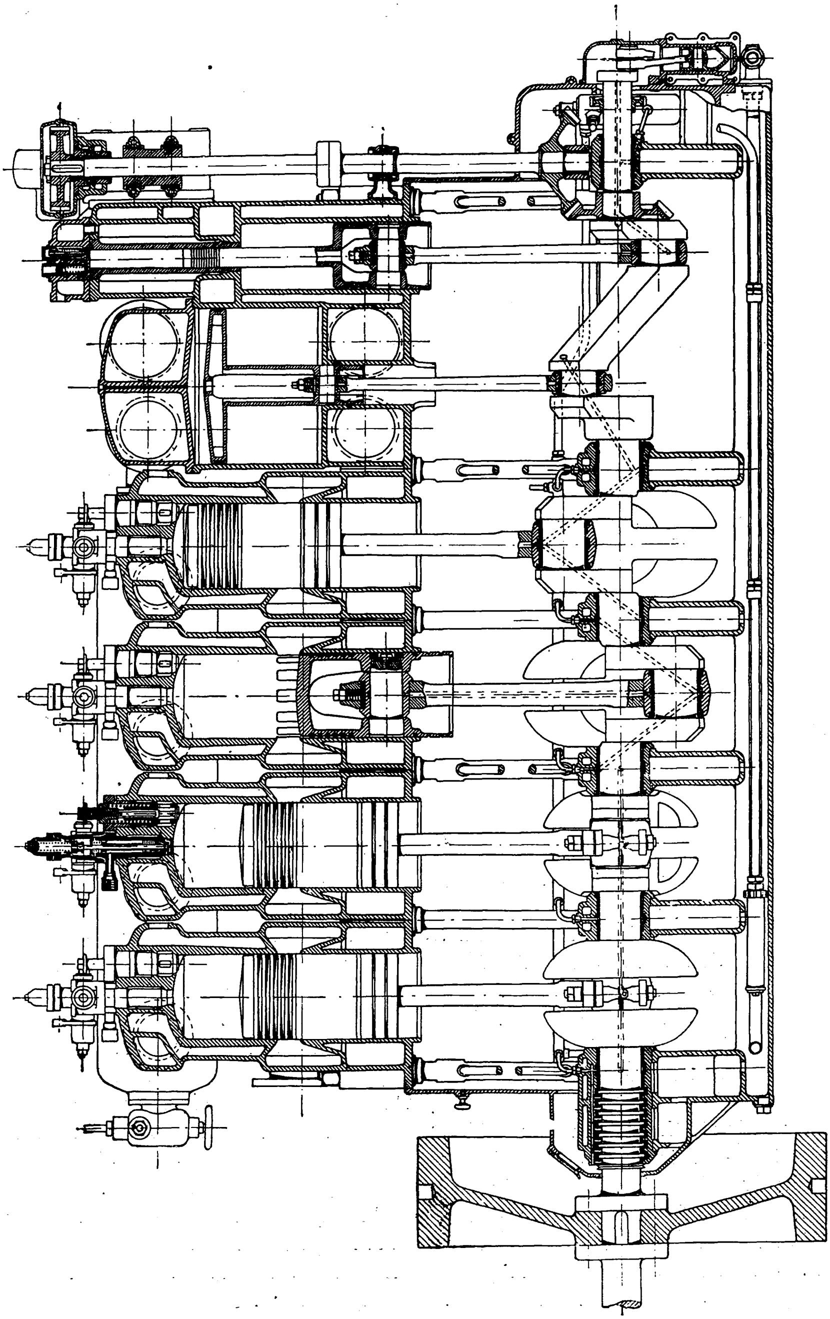

FIG. 40.

Hosted by Google

The following table gives the calorific value, higher and lower, for several types of oils, etc.—

TABLE IV.

Description of Oil.		Specific Gravity.	Hydrogen Content. Per Cent.	Calorific Value, B.Th.U., per lb.	
				Higher.	Lower.
Petrol	Bowley's Special	0·684	—	—	19,190
	Pratt	0·719	—	—	18,610
	Shell	0·767	—	—	18,250
Russolene		0·82	14·0	19,820	18,380
Gas Oil (from brown coal)		0·825	12·3	17,900	16,630
Average "Fuel Oil"		0·89	—	—	18,000
Masut		0·90	13·9	18,600	17,170
Baku Residue		0·928	11·7	11,200	10,000
Coal-Tar Oil (creosote and autracene)		1 to 1·1	6·6	15,800	15,120

In this country petroleum oils, the largest supplies of which come from the U.S.A. and Russia, are used for oil engines. The crude or natural oil contains: (1) Light oils (spirit), specific gravity 0·65 to 0·76, which are used for petrol engines; (2) medium oils, specific gravity 0·76 to 0·86, used for illuminating and for explosion engines; (3) lubricating oils; (4) residues, from which fuel oils for Diesel engines, specific gravity 0·86 to 0·94, are obtained, together with solids such as paraffin wax and pitch.

In 1899 the oil production of the U.S.A. was about ten million tons, and that of all other countries also ten million tons. In 1910 the oil production of the U.S.A. had gone up to twenty-four million tons, and that of other countries to eighteen million tons.

In Germany, owing to the high duty on residue oils—36*s*. per ton—coal-tar oils are principally used with the Diesel engine. Originally the Diesel engine could only use oils having the relatively high proportion of 11 per cent. to 14 per cent. of hydrogen, which excluded tar oils, as they only contain 6 per cent. to 7 per cent. of hydrogen; the reason being that with the usual compression of from thirty to thirty-two atmospheres, the temperature reached is insufficient for ignition. It has been found possible to use tar oils by increasing the compression to over forty atmospheres, but as a practical matter it has been found better to retain the usual compression, and to effect the ignition by a pre-injection of ignition oil, which usually is the oil employed for making oil gas. From 3 per cent. to 5 per cent. of the ignition oil at full load is required, and the heat produced by the burning of this oil raises the temperature to the point required for the ignition of the tar oil.

The Maschinenfabrik Augsburg-Nürnberg Co. use a closed nipple. The ignition oil is injected by a separate pump, and the practice is to use a constant amount for all loads; that is to say, the amount of ignition oil is not regulated by the governor, and only the tar oil pump supply is thus controlled. In the Koerting engine the governor controls both the ignition oil and the tar oil.

The tar oil must be screened to remove solid impurities, and the water must be eliminated. This latter is a difficult matter with tar oils obtained from horizontal or inclined retorts, but the water separates easily from the oil obtained from vertical retorts.

The tar oil must be pre-warmed, say by the exhaust gases, in order to render it fluid, but the temperature must not be sufficient to cause any distillation.

Animal and vegetable oils can also be used in the Diesel engine, and the matter is now receiving much attention from Dr. Diesel.

A fuel-testing laboratory has been established at the University of Zurich under the direction

Hosted by Google

of Professor Constan, and it is probable that a similar laboratory may be established in this country.

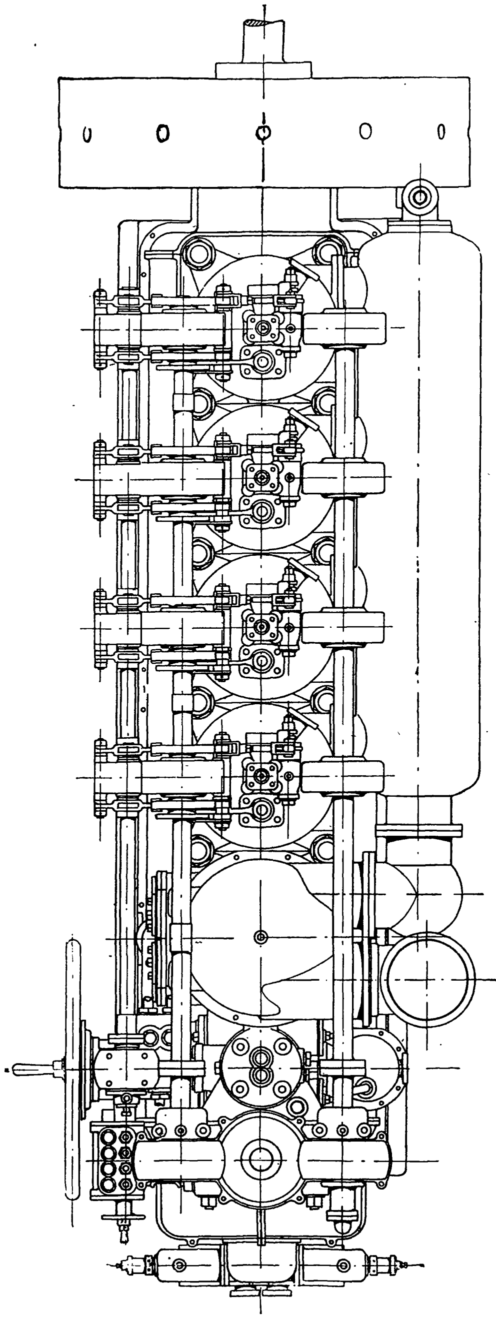

FIG. 41.

From tests and examinations already made, power oils have been divided into the following three classes:—*

* From Dr. Diesel's paper read before the Institution of Mechanical Engineers, March 15th, 1912.

1. Normal oils which can always be used:—

(*a*) Mineral oils freed from benzine (gas oils)	Hydrogen over 10 per cent. Calorific power over 10,000 cal. (39,680 B.Th.U.)* No solid impurities.

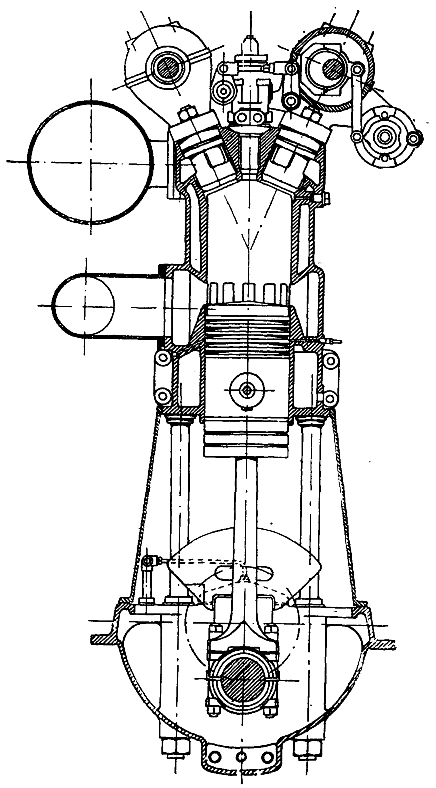

FIG. 42.

(*b*) Lignite tar oils .	Hydrogen over 10 per cent. Calorific power over 9,700 cal. (38,489 B.Th.U.).
(*c*) Fat oils from vegetable or animal sources, such as earthnut oil, castor oil, fish oils, etc. .	Scarcely any researches have been made on these. Earthnut oil has 11·8 per cent. hydrogen, and calorific power 8,600 cal. (34,124 B.Th.U.).

* Higher calorific value per kilogramme.

Hosted by Google

2. Oils which can be used only with the aid of special apparatus:—(*a*) Pit coal-tar oil; (*b*) vertical-oven, water-gas and oil-gas tars, probably also coke-oven tars, the tests on which have not yet been completed.

General characteristics:—hydrogen not over 3 per cent.; amount of free carbon not over 3 per cent.; residue on coking not over 3 per cent.; calorific power not under 8,600 cal. (34,124 B.Th.U.).

3. Oils which cannot be used:—tars from horizontal or inclined retorts.

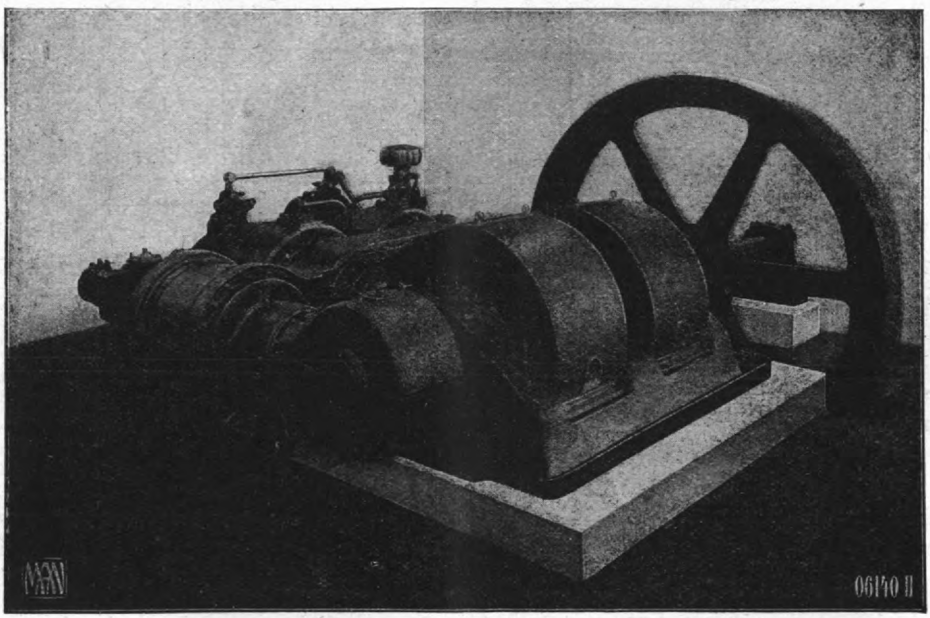

FIG. 43.

It must not be understood that these will not be used in Diesel engines under special conditions; but, on the whole, the above classification is accurate in the present state of development of the Diesel engine.

SPECIFICATIONS OF TAR-OIL SUITABLE FOR DIESEL ENGINES.

(*From the German Tar Production Trust at Essen-Ruhr.*)

1. Tar-oils should not contain more than a trace of constituents insoluble in xylol. The test on this is performed as follows:—25 grammes (0·88 oz. av.) of oil are mixed with 25 cm. (1·525 cub. in.) of xylol, shaken and filtered. The filter-paper before being used is dried and weighed, and after filtration has taken place it is thoroughly washed with hot xylol. After redrying, the weight should not be increased by more than 0·1 gr.

2. The water contents should not exceed 1 per cent. The testing of the water contents is made by the well-known xylol method.

3. The residue of the coke should not exceed 3 per cent.

4. When performing the boiling analysis, at least 60 per cent. by volume of the oil should be distilled on heating up to 300° C. The boiling and analysis should be carried out according to the rules laid down by the Trust.

5. The minimum calorific power must not be less than 8,800 cal. per kg. For oils of less calorific power the purchaser has the right of deducting 2 per cent. of the net price of the delivered oil, for each 100 cal. below this minimum.

6. The flash-point, as determined in an open crucible by Von Holde's method for lubricating oils, must not be below 65° C.

7. The oil must be quite fluid at 15° C. The

Hosted by Google

purchaser has not the right to reject oils on the ground that emulsions appear after five minutes' stirring when the oil is cooled to 8°.

cooling of the oils in the tank during transport, the purchaser must redissolve them by means of this apparatus.

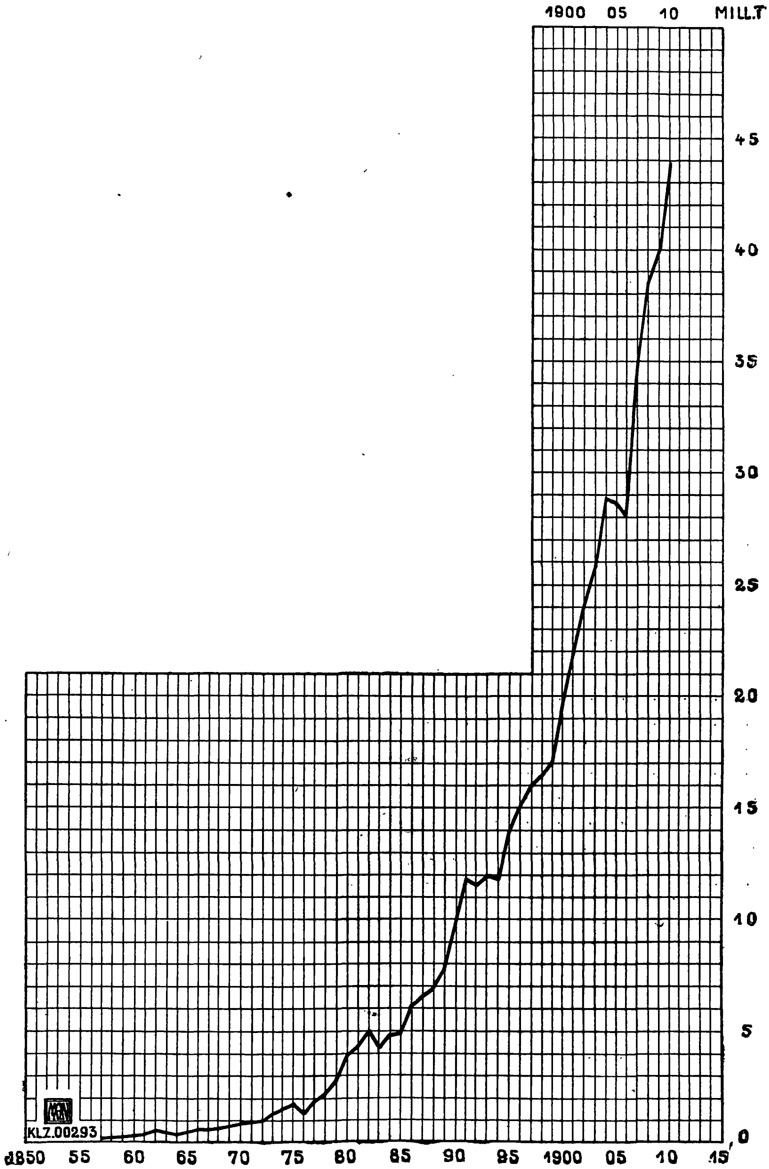

Fig. 44.

Purchasers should be urged to fit their oil-storing tanks and oil-pipes with warming arrangements to redissolve emulsions caused by the temperature falling below 15° C.

8. If emulsions have been caused by the

Insoluble residues may be deducted from the weight of oil supplied.

Fig. 44 shows the world's output of oil from 1857 to 1910 expressed in millions of tons.

THE EFFECT OF HEAVY ROOT-FEEDING ON THE YIELD AND COMPOSITION OF MILK.*

The object of the experiments was to test the effect of a ration consisting largely of roots on the yield and composition of milk, and incidentally to determine how far turnips could profitably replace the more concentrated and expensive foods commonly employed in feeding dairy cattle.

Three separate experiments have been made—the first in 1909, when twenty cows were under experiment; the second in 1910–11, with twenty-two cows; and the third in 1911–12, with eighteen cows. For each experiment two lots of cows, as nearly equal as possible in respect of age, period of lactation, and yield and quality of milk, were selected from the herd. Before the experiment began there was a preliminary period of trial of about three weeks in length, in order to complete the adjustment of the two lots. During this preliminary period all the foods to be experimented with were fed. The cows were then gradually put on to the experimental rations. In experiment III., after the experimental rations had been given for eight to ten weeks respectively, the rations were crossed. The change was effected gradually, so as to introduce as little disturbance as possible, and then the experiment was continued for another four to six weeks.

EXPERIMENT III. (1911–12).

Lot I. (Turnip Ration).

	lbs.
Bean meal	2
Bran	2
Turnips	112
Hay	15

Albuminoid ratio, 1 : 14.

Total dry matter in ration . . . . . 28·6 lbs.

Lot II. (Ordinary Concentrated Ration).

	lbs.
Bean meal	2
Bran	2
Pease meal	4
Dried brewers' grains	2
Turnips	40
Hay	15

Albuminoid ratio, 1 : 7·6.

Total dry matter in ration . . . . . 26·7 lbs.

In addition, straw was fed to both lots.

The turnip ration contained only 4 lbs. of concentrated food as against 10 lbs. in the ordinary ration; on the other hand, it contained 72 lbs. more turnips, and on the average contained about 1¾ lb. more dry matter than the ordinary ration.

The cows on the turnip ration received daily nearly four and a half gallons more water per head than those on the other ration. The results showed: (1) It is not from the ration containing the greatest weight of digestible fat that the richest milk has been obtained. (2) The much larger amount of fat obtained in the milk than was given in the ration. If allowance is made for the indigestible fat in the ration the difference is even more striking. In 1911–12, for example, the turnip ration contained only 171 lbs. of digestible fat, and the ordinary ration only 247 lbs.; the yield of fat in the milk over the amount fed was 358 lbs. in the case of Lot I., and 263 lbs. in the case of Lot II. The larger secretion of fat, which has always been obtained from the cows fed on the turnip ration, appears to indicate that the easily digestible carbohydrates contained in the turnips are specially suitable for fat formation.

Summary and Conclusions.

Taking the results of the three experiments together, we may draw the following conclusions: (1) The feeding of a ration containing a large quantity of water does not increase the percentage of water in the milk, or reduce the percentage of fat. (2) In all three experiments the greater yield of milk was obtained from the cows on the concentrated ration. On the other hand, the milk from the cows on the turnip ration contained a higher percentage of fat, and a greater total weight of fat was contained in the milk.

* Abstract of paper read before the Agricultural Section of the British Association by Alexander Lauder, D.Sc., and T. W. Fagan, M.A.

COTTON-SEED OIL AS A SUBSTITUTE FOR BUTTER-FAT IN CALF FEEDING.*

In most experiments on feeding calves with separated or skim milk and an oil in substitution for the butter-fat, cod-liver oil has been the oil used. Consequently the opinion is prevalent that this is the only oil which can properly be used. The author recently carried out some experiments which were intended mainly as practical demonstrations on the economy of using separated milk and oil in substitution for whole milk in the feeding of ordinary commercial calves. In these cotton-seed oil was used as well as cod-liver oil. Cotton-seed oil was chosen as a comparatively cheap and easily obtained vegetable oil, which is extensively used in human food, and which is known to be wholesome. Another reason why it was chosen was that it was found that practical men, even of the intelligent and educated class, had a profound suspicion of it as a food for calves. This suspicion appeared to be based on the general unsuitability of cotton-cake as a food for young stock.

Three series of calves were fed during the experiments. Each series consisted of three lots treated as follows:—

Lot 1. Fed on whole milk till time of weaning.

Lot 2. Fed on whole milk till three to five weeks old, then whole milk gradually replaced by separated milk and cod-liver oil, or by separated milk, cod-liver oil, and a meal gruel.

* Abstract of paper read before the Agricultural Section of the British Association by James Hendrick, B.Sc., F.I.C.

Hosted by Google

Lot 3. Fed on whole milk till three to five weeks old, then the whole milk gradually replaced by separated milk, cotton-seed oil, and a meal gruel.

After weaning, the calves were all treated similarly till about two years old, when they were sent to the butcher, fat. Records of the weights were kept till the time of slaughter, when the carcass weights and a report on the carcasses by the butcher were obtained.

The following table gives a summary of the results:—

—	Lot 1. Whole Milk.	Lot 2. Cod-liver Oil.	Lot 3. Cotton-seed Oil.
Total number of calves	14	15	15
Average weight at start	109 lbs.	113 lbs.	107 lbs.
Average weight at weaning	309 lbs.	290 lbs.	280 lbs.
Average increase when weaned	200 lbs.	177 lbs.	173 lbs.
Average cost of feeding to time of weaning (per calf)	£3 19*s.* 3*d.*	£1 7*s.*	£1 5*s.* 9*d.*
Average cost of food per pound of increase	4·82*d.*	1·83*d.*	1·79*d.*
Average weight when sent to butcher	1,150·3 lbs.	1,117 lbs.	1,078·3 lbs.
Average increase when sent to butcher	1,041·3 lbs.	1,004 lbs.	971·3 lbs.

The table shows that there is little difference, on the average, between the increases made by calves fed with cotton-seed oil and those fed with cod-liver oil. The cost of the cotton-seed oil feeding was slightly less. There did seem to be a distinct difference in favour of the whole-milk calves till the time of weaning. After that there was no significant difference, and at the time of slaughter the differences between the lots were so small as to be within the limits of experimental error. So far as the evidence of these experiments goes it shows that cotton-seed oil is as suitable as cod-liver oil as a substitute for butter-fat in feeding calves.

THE GUAYULE RUBBER INDUSTRY OF MEXICO.

The growth of the guayule rubber industry in the States of Durango and Coahuila has been truly remarkable. Guayule is a form of rubber extracted from the guayule plant, which grows in enormous quantities in certain of the northern States of Mexico, especially San Luis Potosi, Zacatecas, Durango and Coahuila. As late as 1904, extraction of rubber from the guayule plant was still in the experimental stage, and it was not until the following year that it appeared as an export item to the United States, £26,000 worth of crude rubber being shipped. The guayule shrub grows from one to three feet high, has a thick greyish bark, in which most of the rubber occurs, and has a general appearance not unlike that of the sage brush in the western states of America. It thrives best in the semi-arid regions of central and northern Mexico, on rocky soil, where cactus is almost the only other vegetation. Probably the most luxuriant growth of this plant occurs in the eastern and southern portions of Durango, where much land, which was considered absolutely worthless and not even fit for pasture for cattle, has in the last few years produced fabulous sums from the sale of the guayule shrub.

In 1904, when the guayule industry was in its infancy, the shrub sold for £1 per ton; the following year, £3 to £4 was paid. From that time the price gradually advanced until, at the height of the rubber boom in 1910, as much as £30 per ton was paid. The price during the year 1911, although showing a considerable decline, still averaged over £18 per ton. The Santa Catalina ranch, in the eastern part of the State of Durango, is the source of much of the guayule shrub, and has made a fortune therefrom during the last few years. The plant occurs in the wild state only; several attempts have been made to propagate and cultivate it, but they have all been more or less unsuccessful. The plant is gathered by peons, and is usually pulled up by the roots. These plants are hauled to some centrally located camp, where they are pressed into bales weighing about 330 lbs., convenient for forwarding to the factory.

The method of manufacture is comparatively simple, and consists, according to the United States Consul at Durango, only of three processes, viz., mechanical mastication, washing, and drying. The plant is first ground up into particles about the size of coarse sawdust, which are placed in pebble mills about half filled with hard flint pebbles, with sufficient water to cover the pebbles and the triturated shrub. The mills then revolve at thirty revolutions per minute for two hours. This process serves thoroughly to crush the particles, and to separate the wood from the rubber, which conglomerates in small pellets. Next it is drawn off into settling tanks, where the mixture of fibre and rubber is allowed to settle for

Hosted by Google

several days; the wood, gradually becoming water soaked, goes to the bottom, while the particles of rubber rise to the top and are readily skimmed off. Then the rubber passes through cleansing tanks, which remove the particles of wood and other foreign substances, after which the rubber is subjected to a drying process, and then is run through presses in order to make it into a compact mass of convenient size for transportation. Under normal conditions 10 to 15 per cent. of pure rubber is extracted from each ton of guayule shrub.

Fully 70 per cent. of Mexico's guayule rubber production is worked up in the large rubber factories of the Laguna district, chiefly in the cities of Torreon and Gomez Palacio. There are seven such factories in the Laguna district, which have a combined capacity of a little more than two hundred tons of guayule shrub per day. The plant of one factory at Torreon has a capacity more than equal to that of the other six plants operating in the Laguna combined. This immense plant operates one hundred and twelve large pebble drums, each of which has a capacity for a little more than a ton of the shrub per day. This factory gives employment to about seven hundred men, and is said to be the largest single plant for extracting rubber in the world. The output of finished rubber from this one plant in 1911 amounted to between six and seven million pounds, almost all of which found a market in the United States.

It is estimated that there originally existed 500,000 tons of wild guayule shrub in Mexico, and of this fully four-fifths have been worked up since 1904. Unfortunately the plant is of exceedingly slow growth, and ordinarily requires from eight to ten years to reach maturity. Fear is entertained that the supply will soon become exhausted, and that the large factories which have been built and equipped especially for its treatment will be forced to close. In the last two or three years both the Federal Government and the large rubber companies have been experimenting with the cultivation of this valuable plant with indifferent success. It has been found impossible to propagate successfully from seed on account of the lack of fertility. Some success has been obtained in propagating by shoots from the parent plant, but when these plants reach maturity they possess a far smaller percentage of rubber than is ordinarily found in the shrub in its wild state. Others look at the situation more hopefully, and point out that it has already been seven or eight years since the first plants were gathered, and that within a year or two new plants may be expected with the required amount of rubber contents.

ENGINEERING NOTES.

The Design of Screw Propellers.—The screw was proposed to be used for the propulsion of ships by means of capstans, worked by hand, as far back as 1800, and about forty years later it was introduced to utilise the power of steam for the same purpose, successfully superseding the paddle-wheel. Quite recently aeroplanes and airships have followed this lead. Hence, it would have been thought that everything, theoretical and practical, regarding the design of the propeller would have been well known by this time. It was, therefore, surprising to most engineers who are not specially connected with marine or aerial work to hear that Sir William White, the President-elect of the next meeting of the British Association, stated recently, at the International Congress of Mathematicians at Cambridge, that the marine engineer had no help from mathematicians in designing the propeller, and that no mathematical theory had yet prevailed which had any influence on it as to form, area, or pitch.

Canadian Coal for London.—The coal supply is so important in connection with the engineering industries that it is of much interest to hear that it is proposed to supply the gas companies of the Thames with coal from Nova Scotia. That such a thing could be possible is very significant. The coal measures of Nova Scotia comprise 4,000 square miles, the best and richest of which lie in Cape Breton on the seaboard. The coal is of high quality, and is won in these collieries at a lower cost than anywhere else on the North American continent. Again, Sydney, which is the port of Cape Breton, is less than 2,000 miles from the United Kingdom, and lies in the direct line of navigation between Northern Europe and the great ports of the North American continent. The present output is 6,000,000 tons per year, and is rapidly growing; the larger proportion of this is used up by the great steel works, which have been established locally, but a great portion of the remainder is shipped to places quite as distant from the mines as the United Kingdom. Of course, it is a matter of freights compared with railway rates from home collieries; but in any case the existence of first-class coal within a reasonable distance of our shores is a comforting fact to be considered in the event of future wholesale strikes in this country.

The Machine Tool and Engineering Exhibition at Olympia.—Successful engineering exhibitions were held at Olympia and in Manchester in 1910, and two to follow were announced, one projected by the *Engineering Review*, which was to be held during the present year, and the other by Mr. F. W. Bridges, next year, both at Olympia. Judging that these schemes should be carried out by a representative body of machine and tool manufacturers, some alteration was made, and we have now the exhibition held by the Machine Tool and Engineering Association, which was opened on October 3rd at Olympia. This corporation includes a membership of over a hundred firms, each of which is pledged not to exhibit at any show not approved by the directors. But in one sense the present exhibition does not supersede that of the

Hosted by Google

original proposals, inasmuch as the services of the organising managers of those schemes have been retained for the present one. The result is an exhibition which is much finer than any of its predecessors, not only in regard to the number of its exhibitors, which amounts to 300, but in the variety, interest, and arrangement of the exhibits. A large number of the most important machinery and engineering tool firms are represented; but there is a notable absence of the heavier class of tools, such as those used in shipbuilding yards, marine-engine and locomotive works.

Combustion in Oil and Gas Engines.—*Engineering* points out that many experiments have been made during the past three years to check the rapidity of the explosions in oil-engines, and one method adopted was to let a little water be sucked in with the charge. This greatly increased the ease of running, and made higher compressions possible without danger of pre-ignition. The National Gas Engine Co. use, instead of water, a diluent consisting of the cooled exhaust gases. In this way the rapidity of combustion with rich gases, such as coke-oven gas, is reduced, and higher compressions are practicable. The effect of water is perfectly well known, but in general it lowers the economy. In the case of petrol engines, however, which are often run with mixtures too rich, giving rise to temperatures of about 2,000° C., it might increase the economy to add water to the charge, and this plan is being thoroughly examined. More than a very small addition, however, reduces the economy.

Rails of Copper Alloy.—With the view to securing better power of resistance to wear and tear than is possessed by ordinary steel rails under heavy and fast traffic, the Union Steel Corporation of America are supplying the Chicago, Milwaukee, and St. Paul Railway with steel rails having an alloy of one-sixth of 1 per cent. of copper. There is said to be no material extra expense, and as every year the weights and speeds of railway traffic are becoming greater and greater, the result of the trial of the behaviour of these rails will be awaited by permanent-way engineers with a considerable amount of interest.

Waterproof Concrete.—The United States Geological Survey and the Bureau of Standards have recently published the particulars of some tests which have been made to determine the permeability to water of Portland cement. These show that the concrete is less permeable in the case of mixtures rich in cement, and that the permeability increases with age. The permeability, however, is not dependent altogether on the quantity of cement used, but is also affected by the proportion of coarse to fine aggregate which is employed in the composition of the concrete, that with a large percentage of fine material being less permeable than that with larger particles. Generally speaking, the tests show that concrete may be made practically waterproof at any hydrostatic head, up to forty feet, without the use of any special waterproofing material, of which about forty different kinds were tried. The report points out, however, that this result is only arrived at by the use of the very best materials, put together in the best way, and that the addition of waterproof compounds does not in any way compensate for a lean mixture, poor materials, or improper mixing. None of the compounds tried reduced the absorption materially before the samples were dried by heating at 212° F., but some did decrease the absorption after the samples were so dried. The addition of waterproofing compounds does not appear to have affected the strength of the concrete.

Electrically-driven Vessels.—At the Mare Island Navy Yard, San Francisco, was launched recently the collier "Jupiter." It is the first example of electric ship propulsion on a large scale. She is 572 feet long by 65 feet beam, and has a carrying capacity of 12,500 tons of coal and 375,000 gallons of fuel oil. The equipment will consist of a turbo-alternator and two induction motors. The generator is a six-stage Curtis turbine connected to a bi-polar alternator. The speed at fourteen knots is about 2,000 revolutions per minute, working at about 2,200 volts. Notwithstanding the roundabout conversion of power from steam to electrical and from electrical to mechanical, an experienced authority on the subject expects that the "Jupiter" will show a good steaming economy in comparison with the two sister vessels, of which one, the "Cyclops," is fitted with reciprocating machinery, and the other, the "Neptune," with Westinghouse turbines and reduction gear. The machinery for the "Jupiter" was manufactured by the General Electric Co. of New York. An electrically-driven vessel of 2,400 tons is being built at Wallsend-on-Tyne for service on the Canadian canals and lakes. On this ship there are two high-speed Diesel oil motors, which operate electric generators, and the electric motor turns the propeller shaft.

CORRESPONDENCE.

COLONIAL REPRESENTATIVE GOVERNMENT.

In the *Journal* of October 11th, under the heading of "Empire Notes," mention is made of the claim of the Nova Scotian Assembly to be the oldest legislative body in the present Colonial Empire, with a statement to the effect that this might be contested by Bermuda and Barbados. None of these Colonies, however, was the first in the field, as Sir Charles Lucas has rightly pointed out in his "Historical Geography of the West Indies." Priority must be given to Virginia, which Colony was granted representative institutions in 1619, just one year prior to a similar grant in the case of Bermuda. It must be remembered, too, that a "grant" did not necessarily imply the immediate establishment of parliamentary government. In

the case of Barbados, the patent granted to the Earl of Carlisle in 1627 empowered him and his heirs to make laws "with the consent, assent and approbation of the free inhabitants of the said province or the greater part of them thereunto to be called, and in such form, and when, and as often as he or they, in his or their discretion, shall think fit and best."

There is little doubt that for several years after the first settlement, the government of the island was carried on by the Earl's representatives with a Council chosen by the Governor for the time being, and it was not until after the advent of Captain Philip Bell in 1641, who was appointed Lieutenant Governor, that a proper Assembly was convened. This officer was, in 1645, appointed Governor-in-Chief "for his prudent and moderate deportment during the exercise of his trust as Deputy-Governor."

It is not certain in what year the first meeting took place. There were several Acts passed during Governor Bell's *régime* bearing no date, but he held the office of Governor until May, 1650, when he was succeeded by Francis Lord Willoughby.

G. T. Carter,
Late Governor, Barbados.

GENERAL NOTES.

Brewers' Exhibition. — The Thirty-fourth Annual Exhibition and Market of the Brewing and Allied Trades will be held at the Royal Agricultural Hall, Islington, N., from the 19th to the 25th inst. This year an important feature will be found in the increased number of machinery exhibits, many of which will be shown in motion. The Exhibition is one which, from a business point of view, appeals to a wide circle, besides having a large claim upon the attention of the public in general, affording as it does an insight into the methods of several important industries. The various competitions, too, which have resulted in so much good, are interesting features of this annual show. They number seven — a malting and seed-barley competition, cider and perry, hop, beer, non-intoxicating beverages, Colonial wines and Scotch whisky competitions, the last being introduced this year for the first time.

The Military Aeroplane Trials.—Mr. A. E. Berriman, whose paper on "Aeroplane Efficiency" won him one of the Society's silver medals last session, has just published a little pamphlet entitled "Analysis of the British Military Aeroplane Trials, 1912." It contains tabulated results of the performances of the various machines which competed in the trials held on Salisbury Plain last August, an article by Mr. Berriman on the use of the constant x in the analysis of the trials, and a reply by Mr. G. Holt Thomas. Several interesting and important points are discussed, such as the efficiency coefficients of the competing machines, and their comparative safety. The relation between these two factors is certainly a point that requires careful investigation.

A Year's Work at the Mint.—The report of the Deputy Master and Comptroller of the Mint for 1911 [Cd. 6362] contains the usual detailed statistics, and is illustrated with excellent reproductions of coins, seals, and medals. Illustrations are given of the new Great Seal of England, which resembles the famous Brétigny Seal of Edward III., and of the new Counter Seals of the United Kingdom and of Ireland, in which the King is represented as an Admiral of the Fleet, standing on the deck of a battleship of the "Dreadnought" type. Owing to the Coronation and the Prince's Investiture, there was a large increase in the demand for medals, the number issued being 57,347, as compared with 11,124 in the year before. The gross profit realised by the sale of Coronation and Investiture medals and specimen coins was £6,364 18*s.* 11*d.*, the amount received in cash being £42,599 15*s.* 6*d.* The general account shows a profit of £374,266, as against £1,503,939 in 1910, the decrease being mainly attributable to changes in accounting. The demand for gold coins continued to increase, the number struck being more than two-and-a-half times the average of the previous ten years. About two million fewer bronze coins were struck than in 1910.

The Concrete Institute.—A course of six educational lectures on "Concrete: its Properties and Manufacture," will be given by Mr. H. Kempton Dyson, Secretary of the Concrete Institute, at 5.30 p.m., on November 12th, 19th, 26th, December 3rd, 10th, and 17th, 1912. The lectures will be given in the lecture hall of the Concrete Institute, at Denison House, 296, Vauxhall Bridge Road, Westminster.

MEETINGS FOR THE ENSUING WEEK.

Monday, October 21 ... Brewing, Institute of (London Section), Criterion Restaurant, Piccadilly, W., 8 p.m. Mr. C. Sheather, "The Care and Management of Brewers' Horses."

Sanitary Engineers, Institute of, Caxton Hall, Westminster, S.W. Mr. P. L. Marks, "The Hygiene of Buildings."

Mechanical Engineers, Institution of (Graduates' Section), 8 p.m. Mr. W. J. Maize, "Sewage-Disposal Machinery."

Tuesday, October 22...Photographic, 35, Russell-square, W.C., 8 p.m. Mr. J. McIntosh, "The Autochrome Process." Section I.—Elementary.

Wednesday, October 23...Engineers, Junior Institution of, at the Institution of Electrical Engineers, Victoria embankment, W.C., 8 p.m. Mr. G. C. Allingham, "Scientific Shop Management on the Taylor System."

Royal Society of Literature, 20, Hanover-square, W., 5 p.m. Mr. C. C. Stopes, "The Founders of the Globe Theatre."

Thursday, October 24...Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. Alfred Hands, "Thunder and Lightning."

Friday, October 25...Mechanical Engineers, Storey's Gate, Westminster, S.W., 8 p.m. Professor W. E. Dalby, "Characteristic Dynamical Diagrams for the Motion of a Train During the Accelerating and Retarding Periods."

PROCEEDINGS OF THE SOCIETY.

HOWARD LECTURES.

HEAVY OIL ENGINES.

By Capt. H. Riall Sankey, R.E. (Retired), M.Inst.C.E.

Lecture IV.—Delivered May 20th, 1912.

Testing of Oil Engines.

The testing of Diesel and oil engines is comparatively easy, at any rate so far as measurements of the fuel are concerned, and in this respect presents a great contrast to the difficulties arising in testing steam engines and boilers, or gas engines and producers. The simplest method of weighing oil is to fit the tank supplying the oil to the fuel valve with a pointed hook gauge. Assuming the level of the oil to be above the point of the gauge, as this level sinks a moment will arrive when the point of the gauge will emerge from this surface, and can be snapped on a stop watch. Later, a weighed quantity of oil is emptied into the tank, sufficient in amount again to cover the point of the hook gauge. The moment at which the point again issues is taken on the stop watch, and the interval thus recorded is obviously the time needed to consume the weighed amount of oil; this process can be continued as long as desired, and if the load on the engine is constant and the same weight of oil is emptied into the tank each time, the time intervals ought to be substantially the same.

As regards measurement of power, the engine can either be made to drive a calibrated dynamo, in which case the kilowatts are measured, or a brake is used, usually of the hydraulic type. Fig. 45 shows a 750 h.p. two-stroke engine being tested by means of a Heenan and Froude hydraulic brake.

Fuel Economy at Various Loads.

Fig. 46 shows indicator diagrams taken at varying loads. It will be noticed that the compression is constant, and that the area of the diagram is reduced by reducing the approximately constant pressure part of the diagram, which means that less fuel is used, and that the time of combustion is shortened. The action is similar to altering the cut-off of a steam engine. In this case the revolutions remain constant, which is the usual condition for land engines. In the case of marine engines, however, the load is reduced by diminishing the number of revolutions; in this case the oil consumption per diagram remains approximately what it is at full load, and the brake efficiency also remains nearly constant instead of diminishing as it does when the revolutions remain constant. The effect is that the oil consumption per B.H.P. is more nearly constant at all loads than it is in the case of constant revolution engines. The following published results illustrate this point:—

B.H.P.	lb. per B.H.P. hour.	
	Chalkley.	Sulzer.
400	0·473	0·471
300	0·475	0·471
200	0·496	0·477
100	0·493	0·546

The above results are those obtained on test, but it would appear that they are substantially maintained in actual work. A special advantage of the Diesel engine is that it only consumes fuel when actually running, and it is able to start immediately and stop immediately; this latter advantage is not shared by any other prime heat mover except petrol engines. In the case of the steam engine the steam has to be got up in the

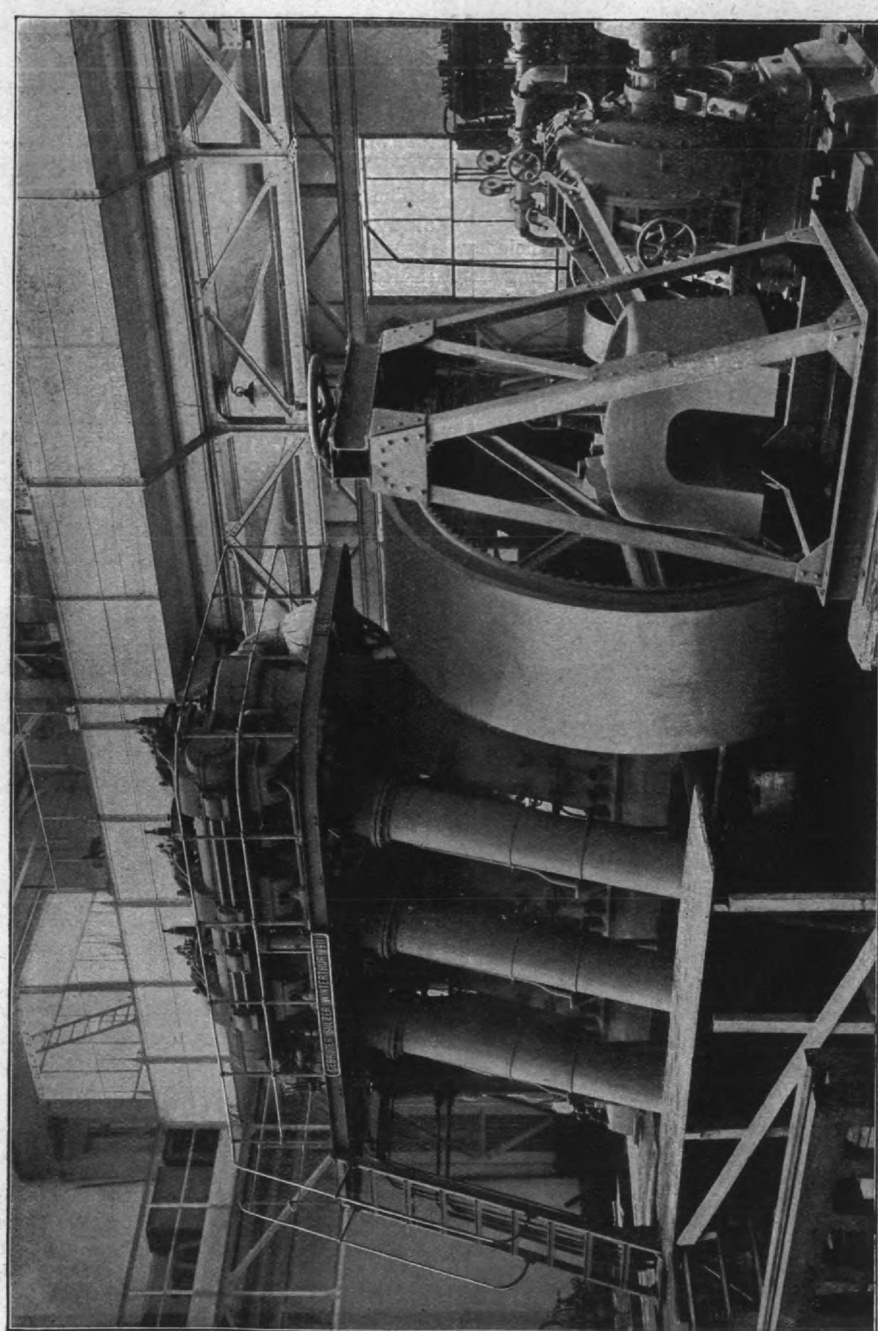

FIG. 45.

Hosted by Google

boiler, and when the engine is shut down there is still a large amount of unutilised heat in the unburned coal on the grate, in the heat in the boiler setting, in the water in the boiler, etc. With a gas engine time is required before the producer can make gas, and when the engine is shut down a considerable amount of fuel is left in the producer. In the case of other heavy oil engines the hot bulb has to be heated by means of a lamp; there is, however, no fuel wasted on stopping the engine.

In Fig. 10, which referred to the case of a four-stroke engine, the brake thermal efficiency was given as 31·0 per cent., and assuming the calorific value of the fuel to be 18,500 B.Th.U.

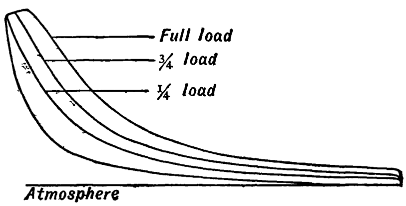

FIG. 46.

per lb., the heat converted into work on the shaft will be 18,500 × 0·319 = 5,740 B.Th.U. per lb. of oil consumed. Hence the consumption of oil per B.H.P. at full load would be 2,545 ÷ 5,740 = 0·443 lb.

In the case of the two-stroke engine the brake thermal efficiency would be reduced to 29·7 per cent., and the oil consumption increased to 0·46 lb. per B.H.P.

The above figures relate to the full rated load of the engine as given in price lists, and the makers generally guarantee a 10 per cent. overload for, say, two hours, but with a slightly increased consumption. As the load diminishes the oil consumption per B.H.P. increases. The following is a typical guarantee, expressed in lb. of oil per B.H.P. (calorific value 18,500):—

Quarter.	Half.	Three-quarter.	Full.	10 per cent. Overload.
0·64	0·50	0·45	0·448	0·458

Considerably better results than these are obtained. Those given in Table VI., published by the Maschinenfabrik Augsburg-Nürnberg Co. (converted to English units and English horsepower) appear to be about the best.

The consumption of Diesel oil engines is always quoted per B.H.P., and this is as it should be in respect of the user; but from the scientific point of view it is desirable to know what the consumption is per indicated horsepower. In this connection it is to be observed that the area of the indicator diagram in the case of the Diesel engine represents a power greater than the true indicated power which is defined as the power produced in the cylinder by the combustion of the fuel. In the case of the Diesel engine a certain amount of the power required for compressing the pulverising air is recovered in the cylinder by admission of the high-pressure air. To give an idea of the effect of this recovery of power, let it be assumed that the oil consumption is 0·45 lb. per B.H.P.-hour, and that the ratio of the B.H.P. to I.H.P. shown by the actual indicator card or "card I.H.P." is 76 per cent.; then the oil per "card I.H.P." will be 0·45/0·76 = 0·342. It may also be assumed that the power shown by the indicator cards of the air-compressor is 7 per cent. of that shown by the indicator card of the engine cylinder, and if 5 per cent. is recovered—that is to say, if the indicator card is reduced by 5 per cent.—then the oil consumption per true I.H.P. will be increased to 0·342 × 1·05 = 0·359.

Mr. Dugald Clerk thinks that the whole 7 per cent. should be deducted, in which case the oil consumption per true I.H.P. would be increased to 0·366. The subject is somewhat difficult, and has not yet been fully considered.

The figures given above refer to full load, and corresponding figures for other loads are given in Table VII. It will be noticed that the oil consumption per I.H.P. diminishes as the load gets less.

In Fig. 47 is shown the heat chart diagram of a Diesel engine, and, for comparison, that of a gas engine, and also of an explosion heavy oil engine. In the case of the two latter, as already explained, the admission of heat theoretically takes place at constant volume, and the abstraction of heat also takes place at constant volume. Assuming constant specific heat, it can be shown that each element of the heat introduced has the same thermal efficiency. Actually, however, the

TABLE VII.

	Quarter load.	Half load.	Three-quarter load.	Full load.	10 per cent. overload.
Per B.H.P.	0 64	0·50	0·45	0·448	0·458
Card I.H.P.	0·29	0·51	0·32	0·342	0·354
True I.H.P. . . .	0·305	0·325	0·336	0·359	0·372

The following comparison* of a slow-speed and a high-speed Diesel engine of 250 to 300 B.H.P., driving a dynamo, will be of interest. Both engines were of four-stroke type, single-acting. They had a two-stage vertical air-compressor, compressing from atmosphere up to fifty atmospheres to seventy atmospheres, and driven by an overhanging crank. The speed could be altered from 400 revolutions per minute to 150 revolutions per minute, the engines being intended for ship-driving.

Description.	High Speed.	Low Speed.
Length	3,655 mm.	4,275 mm.
Width	1,060 ,,	2,000 ,,
Height	2,120 ,,	3,375 ,,
Weight without fly-wheel	11,800 kg.	22,900 kg.
Cost	15% to 20% less than low speed.	
Oil consumption (grammes per B.H.P.)—		
Overload	205	205
Full load	195	195
Three-quarter load .	215	215
Half load	235	240

At full load the brake efficiency in both cases was 0·78.

These engines were worked with the following oils:—Crude naphtha of 0·88 sp. gr.; solar oil of 0·883 sp. gr.; a mixture of 70 per cent. solar oil and 30 per cent. masut 0·88 sp. gr., and with masut 0·9 sp. gr.

It will be interesting to determine what the oil consumption ought to be from theoretical considerations, and it is proposed to do this by means of the heat chart described in Lecture I. (Fig. 8).

* Lee.

specific heat increases with temperature, and the constant volume lines shown in Fig. 47 have been drawn taking account of the increase of specific heat according to the figures given by Mr. Dugald Clerk in his paper for the Institution of Civil Engineers. The effect of this increase of specific heat is to make the slope of the constant volume line for admission less

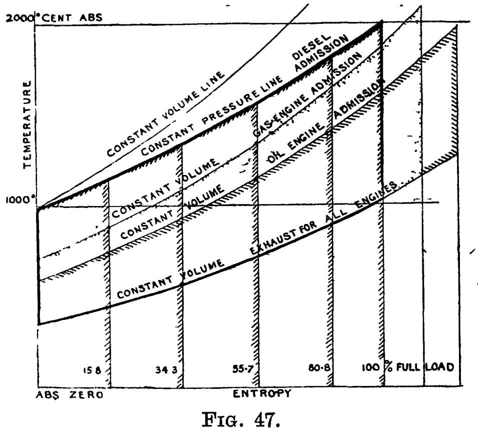

FIG. 47.

than that for the exhaust, and, consequently, the thermal efficiency of elements of heat added at the higher temperatures is less than that of those added at the lower temperatures. This effect, however, is greatly increased in the case of the Diesel engine, as will be obvious from the figure by comparing the constant volume and constant pressure lines drawn through the initial point of combustion.

In the case of the Diesel engine, the power is reduced by diminishing the oil supply, and on

the diagram this is expressed by reducing the area, which corresponds to the amount of heat produced per stroke at full load. Four cases have been taken in Fig. 47, and the percentage of full load is indicated in the left-hand bottom corner of each area. From these the theoretical indicated thermal efficiency for each of these loads can be obtained by measuring the respective areas; this has been done, and the result is given in Fig. 48, and it will be seen that all the points lie sensibly in a straight line, and that the thermal efficiency at no load is 65 per cent. and at 10 per cent. overload it is reduced to 55 per cent.

Results of tests made by the lecturer on a three-throw 225 B.H.P. engine at Messrs. Willans and Robinson's works in 1909 have also been inserted in this figure. It will be seen that the actual thermal efficiency per I.H.P. at the various loads tested also lies very nearly in a straight line. The ratio between the actual thermal efficiency and the theoretical thermal efficiency gives the efficiency ratio, and this has also been plotted on the figure, and it will be seen that the efficiency ratio is greater at light loads than it is at full load within the limits of the test, as might be expected, because within these limits the combustion will probably be equally good, and as the temperatures at light loads are less than at full load there will be less loss, and therefore a better efficiency ratio. At heavier loads and at much lighter loads the combustion may become more imperfect and the efficiency ratio will then be reduced.

Returning to Fig. 48, the reason for the lesser thermal efficiency of the gas engine and of the ordinary oil engine is obvious; in the cases given, at full load the theoretical thermal efficiencies are, respectively: Diesel oil engine, 57 per cent.; gas engine, 51 per cent.; explosion oil engine, 41 per cent.

In Fig. 48 the brake thermal efficiency is also shown, deduced from the experiments for the tests referred to above. The power required for driving the engine was found to be sensibly 69 h.p., and the effect on economy is clearly shown by the curvature of the brake efficiency line. At full load the best figure is obtained; at light loads the improvement in indicated thermal efficiency is overshadowed by the loss due to the brake loss; and above full load, although the brake efficiency is better, the brake thermal efficiency is less because of the reduced indicated thermal efficiency.

The total fuel used per B.H.P. is plotted in Fig. 49 on a load base, and it will be seen that it nearly follows a Willans line, which if produced cuts the origin at a point showing an oil consumption of 19 per cent. of the full load fuel; that is to say, that the engine, when running light, requires 19 per cent. of the full load fuel. On producing the line showing fuel consumption per I.H.P., it is found that 0·28 lb. of oil is required per I.H.P., and as the brake loss is 69 h.p., the oil consumption works out to $0 \cdot 28 \times 69 = 19 \cdot 3$ lbs., which is 19·3 per cent. of the total fuel per hour, namely, 100 lbs., and, therefore in good agreement with the figure previously obtained.

The I.H.P. and B.H.P. lines are also plotted on Fig. 49, and it will be seen that these lines are sensibly parallel, that is, the power required to drive the engine and the air-compressor was 69 h.p. at all loads, and since the full load is 225 B.H.P. the percentage is 30·7. The approximate constancy of the difference between the I.H.P. and the B.H.P. appears to be

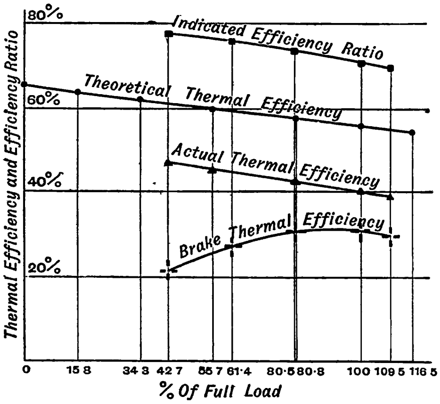

FIG. 48.

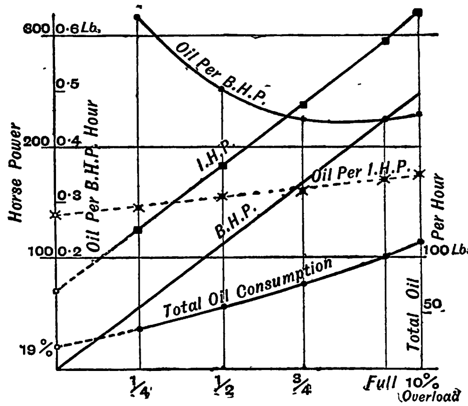

FIG. 49.

general with Diesel engines, as is shown by Table VIII., deduced from actual guarantees, the percentage varying, however, with the size of the engine, whether vertical or horizontal, and whether of the four-stroke or two-stroke type.

Table IX. has been prepared, giving various typical cases, which shows that the Diesel engine is easily at the head.*

In many industries a prime mover is required that has to give occasionally for short periods a considerably greater power than the average.

TABLE VIII.

		33	46	72	78	97
Diesel Engine	18,500	16	25	45	51	—
		19	27	45	50	69

COST OF RUNNING IN COMPARISON WITH OTHER PRIME MOVERS.

It will be of interest to make a comparison of the fuel consumption of oil engines with that of other prime movers, and for this purpose

In such cases the condensing steam engine has an advantage, because it can for short periods

* In most of the items two lines are given. The first refers to an engine whose rated load is 100 B.H.P., and the second to a larger engine capable of developing 150 B.H.P.

Hosted by Google

give as much as 50 per cent. above the rated power. In this connection, it may be pointed out that under similar circumstances the non-condensing engine can give 10 per cent. above the rated power and the Diesel engine can also give 10 per cent. above the rated power, but the gas engine, as usually rated in makers' price lists, can only do its rated power for short periods, and only 85 per cent. of that continuously. It is not only the cost of fuel that has to be taken into consideration when determining which is the best prime mover to use in any particular case, as the interest on capital, labour, depreciation, repairs, etc., must also be taken into account. To give some idea what this means, Table X. has been prepared. Assuming that the average load is 200 B.H.P., and that for short periods 300 B.H.P. is required, the rated powers of various prime movers would, therefore, be as follows:—

Non-condensing steam engine . .	270 B.H.P.
Condensing steam engine	230 „
Overtype superheated condensing steam engine	230 „
Gas engine	300 „
Oil engine	300 „
Diesel engine	270 „

In Table X. the estimate for capital cost includes boilers, foundations, producers, building, etc. The cost of repairs, maintenance, and labour, has been also estimated, and the plant is assumed to be run for 3,000 hours per year. The cost of fuel has been taken as follows:—

Oil	42s. per ton.
Coal for pressure producers . . .	18s. „
Coal for suction producers . . .	28s. „
Coal for steam boilers	18s. „

It will be seen that the annual cost of running the overtype superheated steam engine is £53 less than that of the Diesel engine when all conditions and items of expense are taken into consideration. The conditions assumed are not at all unusual for small plants, but obviously they may be so varied as to produce very different results, and each case must be considered on its own merits, but the above will give an idea how to proceed. Especially is it easy to make a correction should the price of fuel vary from that given above. Thus if the price of fuel oil is increased to 55s. a ton, the cost for fuel for Diesel engines would be $252 \times \frac{55}{42} =$ £330, and hence the annual cost would be increased to £1,010.

[A number of slides were exhibited, showing applications of the Diesel engine to various purposes, such as driving a cotton mill, application to power-stations of various kinds, marine propulsion of torpedo-boats, yachts, tug-boats as auxiliaries for large sailing vessels, and Durtnall's application to a locomotive, in which a Diesel engine drives an alternating dynamo —which in its turn drives induction electric motors placed on each axle.]

Fig. 50 shows an electric power-station driven by vertical engines, and Fig. 51 a similar station

driven by horizontal two-stroke double-acting Diesel engines of 2,000 B.H.P., in both cases made by the Maschinenfabrik Augsburg-Nürnberg Co.

VARIOUS HEAVY OIL ENGINES.

The preceding remarks refer principally to Diesel engines. There are many other heavy oil engines on the market, both of the explosion and of the combustion type, and the following have been selected as being representative of the various types :—

The Hornsby-Ackroyd engine is one of the earliest of the explosion engines, and it is understood that some 40,000 of them have been made. Fig. 52 shows a section through the cylinder of one of these engines, and Fig. 53 gives an enlarged view of the vaporiser valve-box. The relief valve is regulated by the governor; the oil pipe delivers a constant amount per stroke, and the amount not required to deal with the load flows back into the tank through the relief valve. The compression has to be adjusted to suit the oil in use; the most usual oil for these engines is Russian oil of a specific gravity of 0·823 to 0·825, but they also work satisfactorily with Texas oil of 0·933 sp. gr. The oil consumption is stated to be 0·674 lb. of Texas oil. These

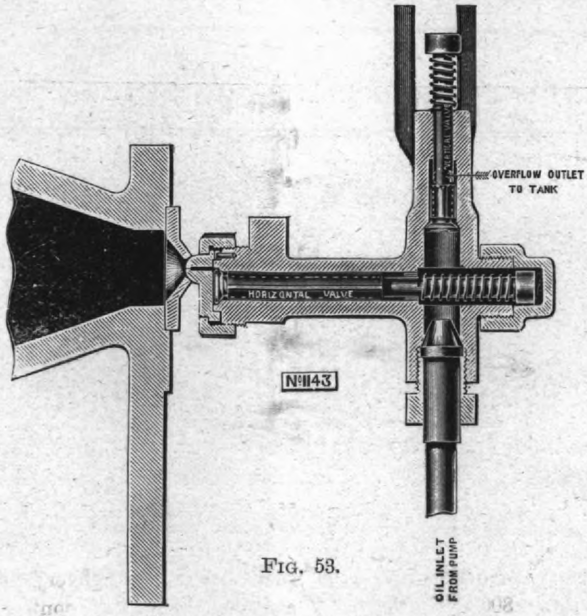

FIG. 53.

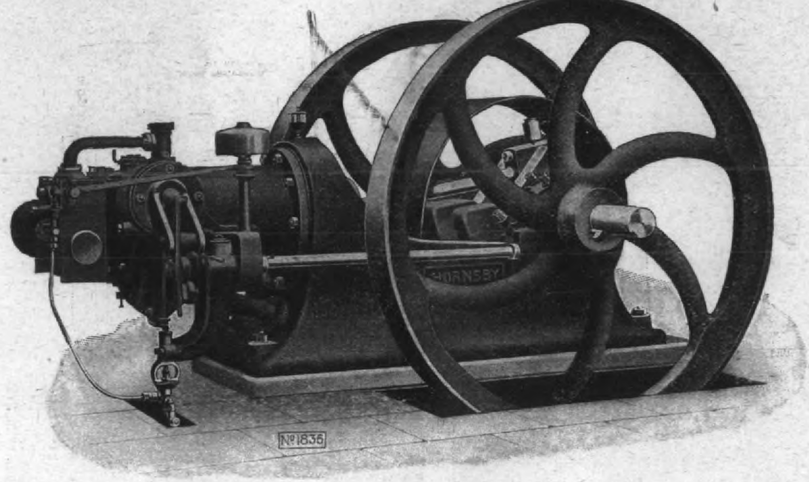

Fig. 54.

engines are listed to about 370 B.H.P., and Fig. 54 gives an outside view.

The Allen engine is shown in Figs. 55 and 56. It is an explosion engine with a hot-pot vaporiser; a blow-lamp is used for heating the hot-pot for starting, or the engine may be started on petrol. The ignition is also ensured by a magneto, and through the valve pocket. As the piston nears the top of its stroke the supply through the valve pocket is cut off and a charge of air at 150 lbs. pressure is trapped in this valve pocket. The fuel is injected at the top of the stroke in a fine spray by means of the special pump, a section of which is given in Fig. 59. There are two

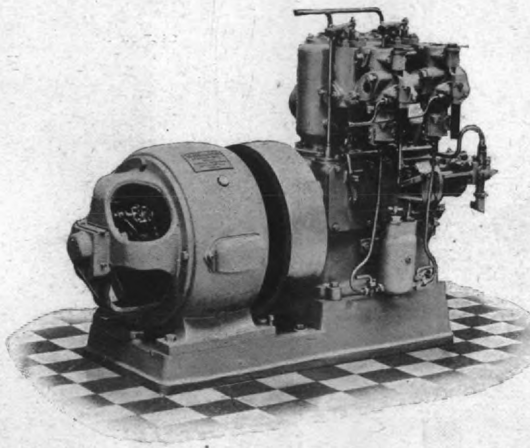

Fig. 55.

these engines use paraffin oil of 0·82 sp. gr., and are built from 2½ B.H.P. at 800 revolutions to 75 B.H.P. at 500 revolutions.

The Cross engine, built by the Westinghouse Brake Co., is shown in Figs. 57 and 58. As will be seen, it has a divided combustion chamber, and there are two air inlets, one through the combustion chamber and a second suction and two delivery valves driven by a cam and under the control of the governor. The fuel injected into the hot compression chamber ignites, no matter how small the load may be, and on the piston descending the air charge trapped in the valve pocket completes the combustion. The hot bulb is of small size, and only requires about three minutes to heat

Hosted by Google

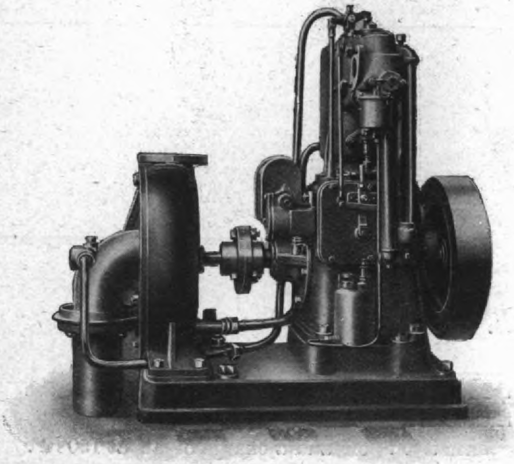

FIG. 56.

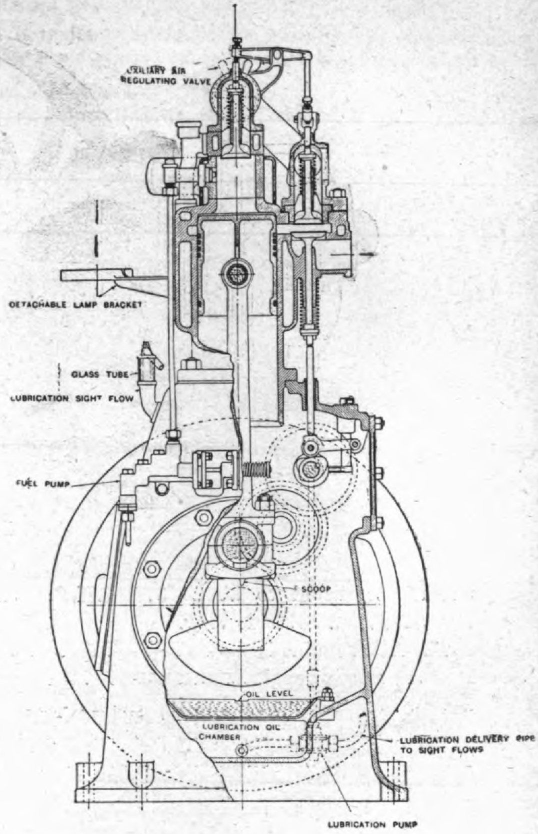

SECTION OF 10 H.P. CROSS OIL ENGINE

FIG. 57.

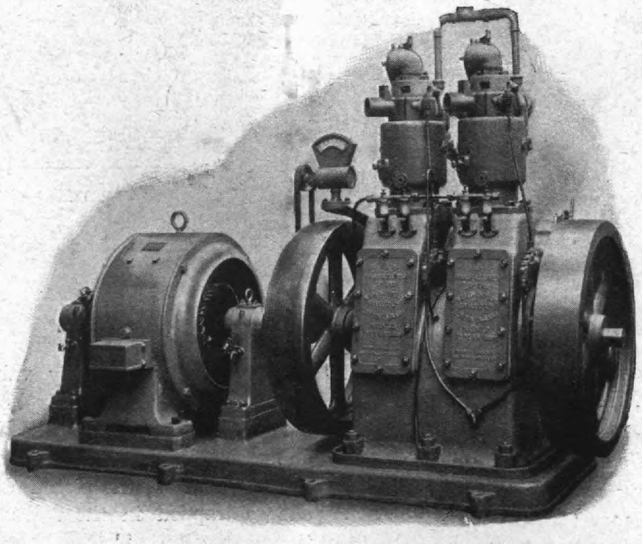

FIG. 58.

it by a blow-lamp. These engines are built up to about 40 h.p. in four lines (illustrated by several slides). The specific gravity of the oil used is 0·85. In this engine it is probable that a portion of the oil is exploded, followed by combustion. The engine may therefore be said to be partially of the explosion and partially of the combustion type, or, as they are sometimes called, of the semi-Diesel type.

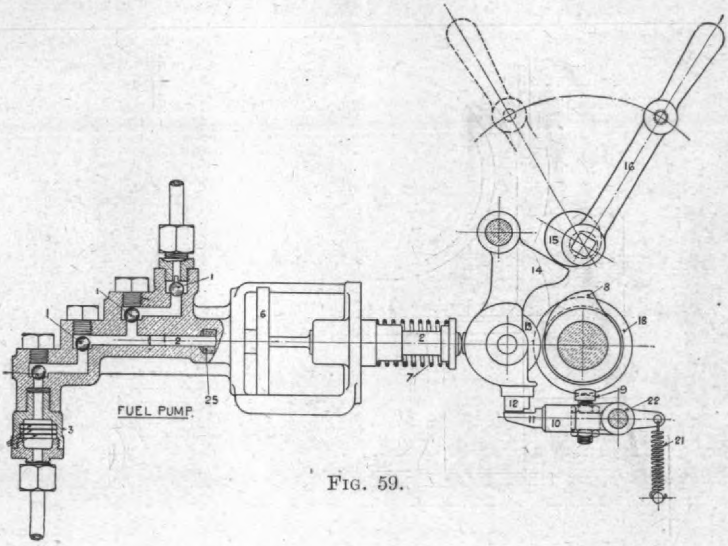

FIG. 59.

The Ruston - Proctor engine is shown in Figs. 60, 61 and 62, the last of which gives a section through the cylinder breach. Like the Diesel engine, it compresses pure air, but the compression, which is from 270 lbs. to 280 lbs. per square inch, produces a temperature insufficient to ignite the oil, and the necessary temperature has to be obtained by the addition of a hot bulb. This engine is, therefore, also of the so-called semi-Diesel type. The hot bulb is heated by a lamp to a dull red before starting, an

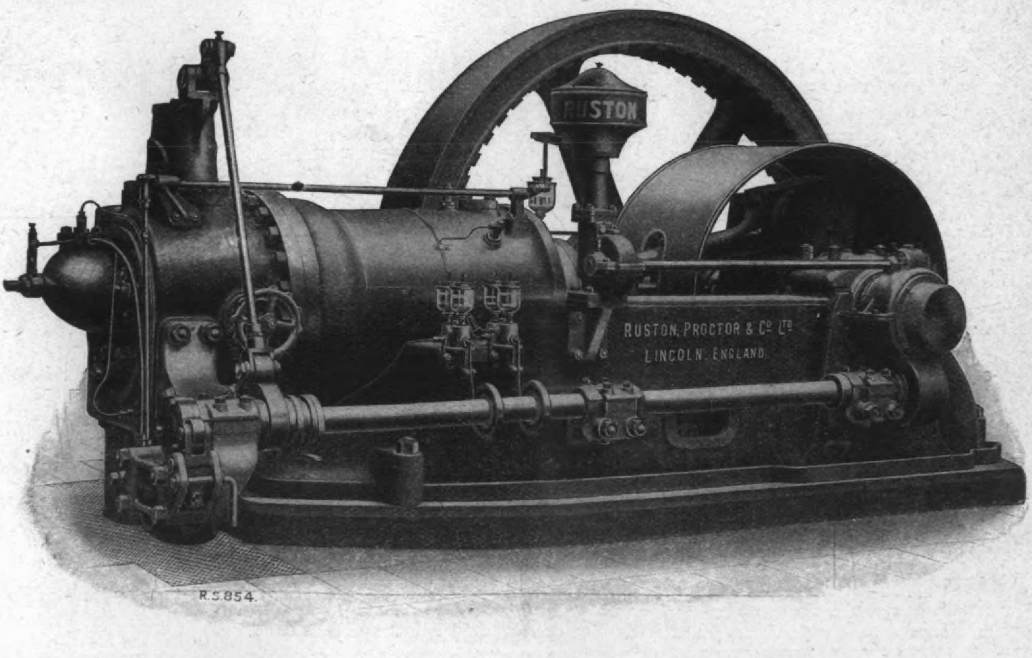

FIG. 60.

Hosted by Google

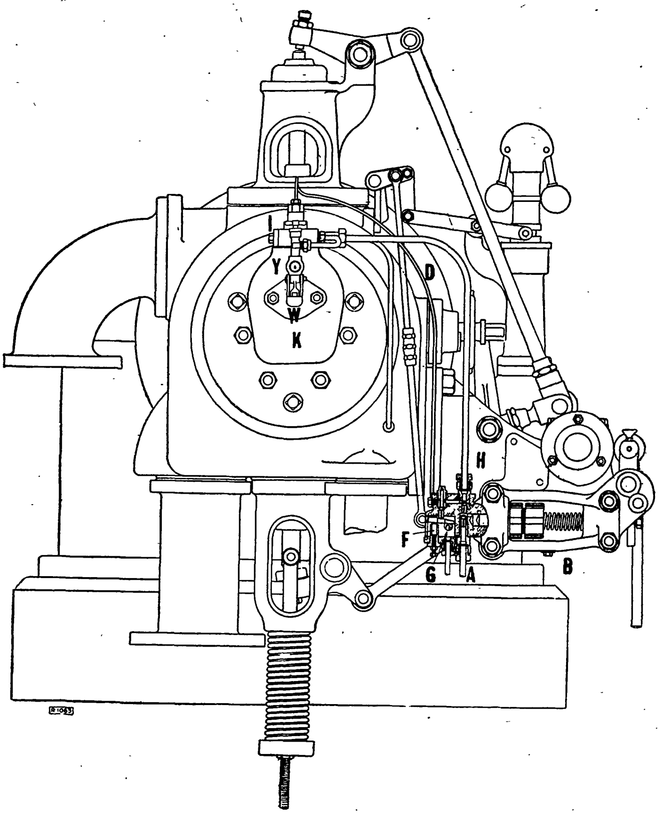

Fig. 61.

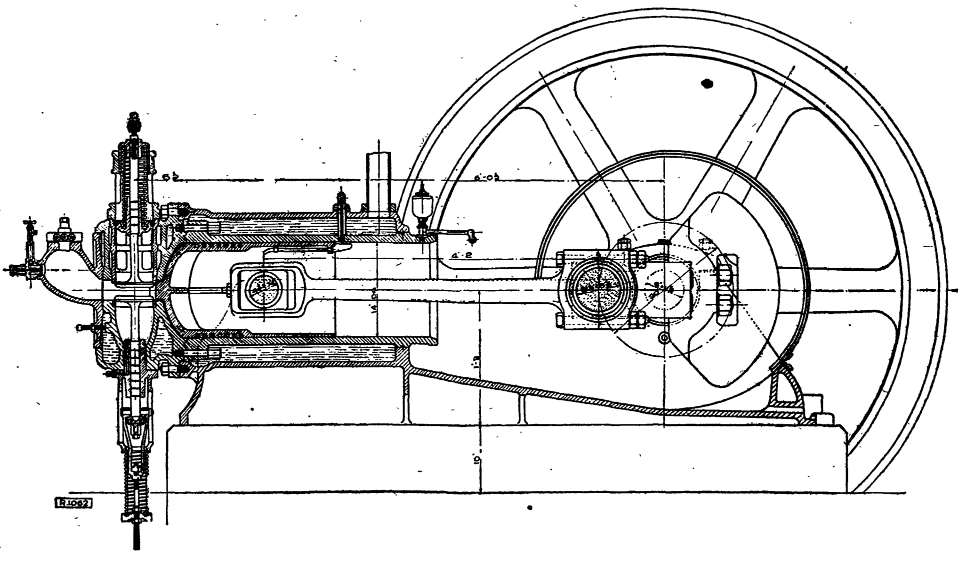

Fig. 62.

Hosted by Google

operation which requires about twenty minutes, and it is maintained at this temperature during running by a water injection. The mean pressures obtainable are 84 lbs. with crude oil, and 80 lbs. with Italian refuse. The oil consumption is 0·45 lbs. and 0·49 lbs. per B.H.P. hour respectively, according to test made by Professor Robinson on a 50 B.H.P. engine. A speciality of this engine is the way in which the fuel is injected: a needle valve is lifted by the action of the pressure produced by the oil fuel pump, and a swirling motion is given to the oil by means of a special device. The governor actuates a by-pass which opens the instant the necessary fuel has been injected, thus reducing the pressure and causing the needle valve to drop and shut off the oil.

The Petter engine is a two-stroke engine of the semi-Diesel type. The scavenging air is compressed in the closed crank-chamber on the down stroke of the piston. This air clears out the exhaust products, and on the up stroke pure air is compressed to a moderate pressure and the fuel oil is injected by a pump, and by a special arrangement is intimately mixed with the compressed air.

[One of these atomisers was exhibited and explained at the lecture.]

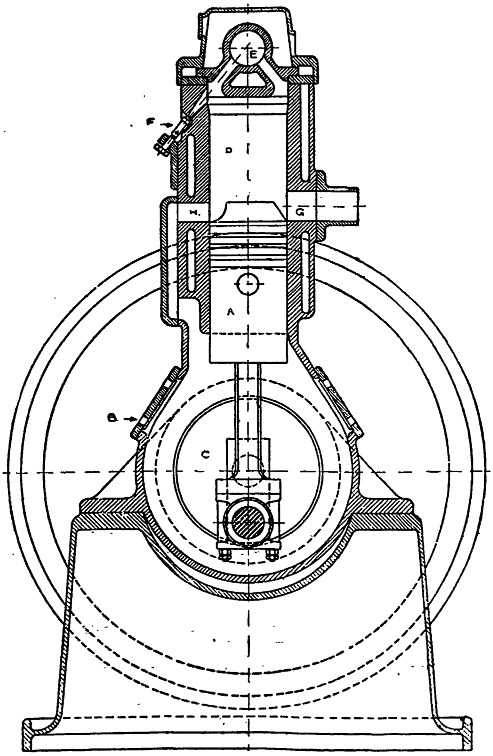

Fig. 63.

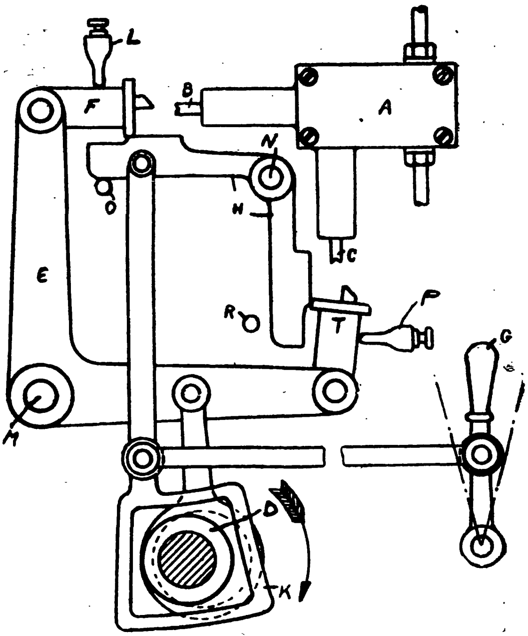

Fig. 64.

These engines work with "fuel" oil of 0·93 sp. gr., and the consumption of oil of 0·93 sp. gr. is stated to be 0·47 lb. per B.H.P. hour.

The Bolinder engine is of the explosion-combustion type; the makers, like many others, object to the name "semi-Diesel." Its action will be easily realised from Fig. 63. Just before the bottom of the stroke the exhaust valve, *G*, is uncovered, and almost immediately after the port, *H*, opens and admits the scavenging air compressed in the closed crank chamber by the descending piston which sweeps out the remaining products of combustion. By the special shape given to the top of the piston, this air finds its way into the hot-pot, *E*, to clear out the exhaust products there. These engines are made in from one to four lines, and from 5 to 320 B.H.P. The consumption of Scotch shale oil varies from 1 lb. to 0·6 lb. per B.H.P. hour, according to the size of the engine. At heavy loads water is injected into the hot-pot to prevent it getting too hot, and thus "cracking" the oil. These engines are principally intended for the propulsion of small ships, such as fishing vessels, etc., and very large numbers have been supplied for these purposes. The reversal of the engine is effected by means of an apparatus diagrammatically shown in Fig. 64. There are two fuel pumps, the plungers of which are marked *B* and *C* respectively; *A* is the fuel pump; *B* is the normal pump worked by the

Hosted by Google

pecker *F*, actuated as shown in the figure. The full pump supply only comes into action when the direction of rotation of the engine is to be changed either from ahead to astern, or from astern to ahead. To change the direction of the engine from that shown by the arrow, the lever, *G*, is pulled over to the right; this brings the link, *K*, into contact with the friction wheel, *D*, and by means of the mechanism shown puts the

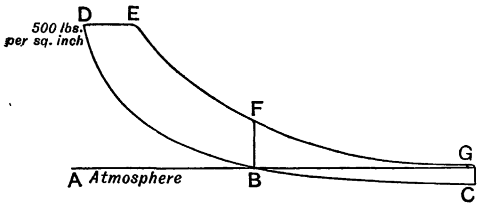

Fig. 65.

pecker, *F*, out of action, bringing pecker, *T*, into action. The pump, *C*, is so timed as to inject the charge of oil before the piston reaches the top of the stroke; this checks the up stroke and drives the piston down in the reverse direction.

An engine has recently been proposed by Mr. Durtnall, which is of the Diesel type, but the suction valve is arranged to close before the end of the out stroke, so that, as shown in Fig. 65, pure air is drawn in from *A* to *B*, and this air is expanded along the line *BC* to the end of the stroke at *G*. The reduction in pressure at the end of the stroke acts as an air cushion, arresting the motion of the parts and reducing the bearing pressure. On compression of the stroke the indicated diagram follows the line *CBD*, and the compression space in the cylinder can be so arranged that the pressure at *D* shall be 500 lbs. per square inch needed for heavy oil ignition. *DE* shows the full admission as in a Diesel engine, and the expansion *EFG* is extended to atmospheric pressure. The exhaust of this engine would therefore be at constant pressure. *BDEFB* would be the diagram of the corresponding Diesel engine. The theoretical thermal efficiency of this type of engine would therefore be greater than that of the pure Diesel engine.

In conclusion, the following chart is given, discriminating between the various types of light and heavy oil engines.

OIL ENGINES.

Heat Admission at

Constant Volume.	Constant Pressure.	Partly Constant Volume and Pressure.
Explosive mixture is produced by vaporisation of the oil either at atmospheric temperature (light oils) or at a higher temperature (heavy oils).	Pure air is compressed in the cylinder, and the oil is introduced just before the turn of the stroke.	
Compressed in the cylinder prior to explosion by a hot tube or bulb, or by an electric spark.	Ignition is caused by the temperature of the compressed air.	Ignition is caused by the oil striking against a hot surface.
Compression limited upwards to avoid pre-ignition.	Compression limited downwards to ensure ignition.	Compression unlimited over considerable range.
Low Compression.	High Compression.	Medium Compression.
80 lbs. per square inch.	500 lbs. per square inch.	200 lbs. per square inch.
Sp. Gr. 0·68 to 0·72 | 0·82	Up to 1·2.	Up to 0·9.
< LIGHT OIL ENGINES > | < HEAVY	OIL	ENGINES. >

THE FOREIGN TRADE OF CHINA, 1911.

The statistics of the foreign trade of China in 1911 not only show but little trace of the general upheaval caused by last year's revolution but constitute a record, exceeding as they did the figures for 1910, which were 11½ per cent. more than in any previous year. Considering the vast extent of the country, and the commercial aptitude of its enormous population, the foreign trade of China, which amounts to about the same value as that of Switzerland, may be said to be still in its infancy. At the end of 1910 there was a financial crisis in Shanghai, the commercial metropolis, resulting from wild speculation in rubber and from the breakdown of the native banking system. The Yangtze River rose to unprecedented heights, and vast tracts of country were inundated, rendering millions of people homeless and destitute. Serious summer floods occurred also in Chekiang, in Shantung, and in the Liao River valley in Manchuria. In August fresh trouble was caused by delays in deliveries of goods due to labour strikes in the United Kingdom, whereby clearances were retarded, and when this trouble was righting itself, the wealthy province of Szechuan, where the crops were excellent, was cut off as a customer by the widespread agitation against the central government's railway policy, which was the forerunner of the October revolution.

This revolution, though its effects were not fully perceptible in the customs statistics for 1911, nevertheless inflicted a crushing blow on the trade of China. From the date of the revolt of Wuchang on October 10th the whole banking system of China broke down, and it was to this financial crisis rather than to the revolution itself that the complete stagnation of trade at the end of the year must be mainly attributed. By the time that the weaker banks were eliminated, and the financial horizon in Shanghai began to clear, the country everywhere had become so unsettled that neither goods nor money could be moved freely.

In the Canton province piracy and brigandage materially affected the supplies to consuming and distributing markets, and though of course the circumstances varied in different provinces up to the end of the year, the conditions were nowhere normal. The establishment of a republican government has opened up a prospect of settled conditions and revived trade, and, given the restoration of order in the interior, commerce will no doubt quickly respond. The general feeling, however, amongst merchants in China seems to be that anything in the nature of a boom is not only unlikely but undesirable, for experience shows that reaction is the almost invariable sequence, whereas if conditions become normal trade will develop gradually and healthily.

The chief articles of import into China admit of being classified into few prominent heads. Opium, formerly so important, is now diminishing rapidly, owing to the agreements between the Indian and Chinese Governments, the latest of these compacts having provided for the complete extinction of the export in 1917, or at an earlier date, if clear proof be given of the complete absence of production of native opium in China. The following table of imports of plain cottons, *i.e.*, shirtings, sheetings, drills, jeans and T-cloths, indicates the share taken by the chief manufacturing countries during the last five years:—

Nationality.	1907 Pieces.	1908 Pieces.	1909 Pieces.
British . . .	8,224,951	8,993,534	10,691,448
United States .	578,647	1,586,989	3,856,231
Japanese . .	840,401	986,982	1,396,297
Indian . . .	67,905	141,312	133,855

Nationality.	1910 Pieces.	1911 Pieces.
British	6,551,126	11,317,630
United States	1,385,819	1,988,061
Japanese	2,389,693	2,832,625
Indian	147,952	21,935

From the above it will be seen that British goods show a still larger and gratifying development, the increase in British jeans at Newchwang in substitution of the American imports being specially noticeable. But the most salient feature of the cotton trade in 1911 was the decrease in the imports of Indian and Japanese cotton yarn to 248 million lbs. in 1911 as against 304 million lbs. in 1910.

Cigarette smoking, which has led to such enormous imports into India, has had to encounter in China an agitation carried on with varying success in Shantung, Kiangsu, Chekiang, Szechuan, Yunnan, and other provinces for the suppression of the practice of smoking. This repressive movement has been encouraged, curiously enough, by the Protestant missionaries, as well as by the Chinese themselves, the latter apparently through dislike of consuming foreign products. The anti-cigarette campaign seems to have been most active in Hangchow, but to have failed in Nanking. At Cheng-tu, the capital of Szechuan, the determined opposition of British and American missionaries was more than counterbalanced by the increased sales of cigarettes to Chinese soldiers there ever since the revolutionary troubles in September.

Another effect has been the signs of revolution in Chinese dress, and an enormously increased demand for foreign hats and caps, and to a lesser extent for foreign boots and shoes, foreign hosiery and underclothing, and even foreign suits of clothes. In spite, however, of the remarkable changes of

Hosted by Google

fashion which meet the eye, and which are certain to go on increasing, these will nevertheless fail to be adopted by the mass of the population. The trade in artificial indigo continues to develop, especially in Hunan, where it was formerly unknown, and it has almost displaced vegetable indigo in Chinese dye-works in Manchuria. The business is entirely in the hands of German firms. American flour has been imported in largely increased quantities, especially at Chefoo, this being attributed to the failure of Chinese harvests from floods or other disasters. In machinery, railway material, vehicles, etc., business was dull throughout the year. The figures for kerosene oil again showed an enormous increase, this increase being most marked in American oil, which rose over 50 per cent.

The total value of exports in 1911 fell short of that of 1910 by less than £500,000, but there is no doubt that had it not been for the revolution the export trade of 1911 would have far exceeded any previous record. In value, silk products head the list with a percentage of nearly 25 per cent. of the total, the other chief exports being tea, beans and bean cake, raw cotton, skins, hides and furs, seeds (sesamum) and vegetable oils.

With regard to the shipping trade, one noteworthy feature is the rapid development of the homeward trade from the German port of Tsingtau, which during the past year has become a regular calling port for all the principal Europe-bound lines. The coasting trade, in which British capital and enterprise are still largely predominant, between Shanghai and the Yangtze and northern ports is said to have been until the revolution started in a more flourishing condition than for some years past. On the Yangtze the allied steamship companies (two British and one Chinese) have still to face a serious competition from Japanese lines, heavily subsidised by the Japanese Government, but the French company which for several years ran three steamers between Shanghai and Hankow withdrew last year from the field, their steamers being purchased by the two British companies.

In the domain of railway construction three events of interest are recorded, viz., the opening to traffic of the Kanton-Kowloon railway, the completion of the reconstruction by the Japanese of the railway from Mukden to Antung, and opening to traffic of the same, so that trains can run through over the Yalu bridge to Seoul and Fusan, and the practical completion of the lengthy line from Tientsin to Pukow, on the Yangtze opposite Nanking. The only gap on this line was caused by the delay in the bridge over the Yellow River, but it is hoped it will be completed in the autumn of 1912.

No marked development in the coal-mining industry in China took place in 1911, though each of the principal mines in the north showed an increased output. Many plans have been made and sent in for working the rich mineral deposits of Hunan Province, mainly copper, tin and gold, but, as is well known, Hunan is an anti-foreign province, and the objection to the use of foreign capital is apparently very deep-rooted there.

The record of fresh industrial enterprises established in China during the year is very interesting, including electric light installations, candle, bricks, cement, match and many other factories, a proof of the widespread wish throughout the country to enable native manufacturers to compete successfully with goods imported from abroad.

ARTESIAN WELLS.

In connection with the subject of the artesian well at the Institution of Civil Engineers, described in the *Journal* of the 11th inst., it may be of interest to mention that from time to time a number of deep artesian wells have been sunk in different parts of the metropolis many years back in the last century, notably in the case of the Bank of England, 334 ft. deep (1852), Trafalgar Square fountain, 396 ft. deep (1847), Meux' Brewery, Tottenham Court Road, 360 ft. deep (1843), subsequently deepened to 1,144 ft. in 1876, the Victoria railway station, 360 ft. deep (1861), and a good number of breweries, distilleries, and large manufactories. These consisted of deep shafts first sunk into the London clay, from the bottom of which boreholes were made into the chalk, whence the water flowed up into the shaft.

It is, however, more particularly of late years, during which the shafts have been dispensed with and replaced by the more economical bored-tube wells, that a considerable increase in the number of artesian wells has been made for public baths, electric generating stations, and other purposes, including, more recently, tube railway stations and tramway depots, and numerous establishments besides manufactories, such as the offices of large commercial firms, extensive blocks of city offices and residential flats, etc.

Amongst these a few may be mentioned, such as the wells for the Central London tube railway at Shepherd's Bush, 380 ft. deep, the metropolitan public baths of St. Pancras, 400 ft. deep, the Borough of Bethnal Green public baths, 500 ft. deep, the London County Council tramway depot at Greenwich, 350 ft. deep, the Borough of Hackney electric generating station, 450 ft. deep, City office buildings in Mincing Lane, Gracechurch Street, Lombard Street, and London Wall, the Norwich Union Life Assurance offices, St. James's Street, the Anglo-American Oil Company's offices, Queen Anne's Gate, and the Amalgamated Press offices, Farringdon Street, of various depths ranging from 400 to 500 ft. deep; also residential flats in Ashley Gardens, Victoria Street, S.W.

The depth at which the chalk is reached varies considerably, ranging from 82 ft. at Hackney and 105 ft. at Greenwich, and 161 ft. at St. Pancras to 234 ft. at Queen Anne's Gate, and 256 ft. at Ashley Gardens.

Hosted by Google

The quantity of water yielded also differs considerably, according to the district, the porosity of the chalk at the site, and the capacity of the pump employed, and may range from 5,000 gallons to 50,000 or 80,000 gallons per diem.

[The above information has been furnished by Mr. Alfred Le Grand, of the firm of Messrs. Le Grand & Sutcliff, who carried out the work at the Institution of Civil Engineers.]

THE MANGROVE INDUSTRY OF MADAGASCAR.

The production of red mangrove bark in appreciable quantities for export in Madagascar has considerably developed since 1905. In that year the quantity exported was only about 137 tons, valued at £450, while for the year 1910 the figures were 36,131 tons, valued at about £106,000. The mangrove forests are in the Provinces of Nossi-Bé, Analalava and Majunga, on the north-west coast of the island, bordering on the Mozambique Channel. In the first two provinces the approximate areas of mangrove trees amount to about 80,000 and 49,000 acres respectively. On account of the density at certain points in Majunga, it has been impossible to ascertain, even approximately, the area of the mangrove forests in that province. It is believed, however, that the total area of mangrove trees in the three provinces is between 75,000 and 100,000 hectares (185,000 to 247,000 acres). The mangrove trees are generally grouped at the mouths and on the banks of the numerous rivers, and at the ends of the numerous bays in the three provinces mentioned. Quantities of trees are also found along the immediate coast, and in some instances, especially in the Province of Analalava, they extend more than six hundred feet into the sea, their working being facilitated by the fall of the tide. In most of the bays, and in several of the largest rivers, steamers enter to receive the bark. The average size of the mangrove tree is from 20 to 40 inches in circumference and 100 feet in height. The above figures and estimates, as regards area and density, relate to mangrove trees in general, of which there are several species, only two being useful for tanning purposes, the *anabovahatra* and the *tsitolony*. The proportion of these to the total area of mangrove trees is unknown. The *anabovahatra* is said to contain 60 per cent. of tannin, and the *tsitolony* only 30 per cent. The latter, because of its inferiority, has been worked very little, owing to the fact that there has always been an abundance of the former. The *anabovahatra* is also much used for construction timber. It is said that the heart of the tree is equivalent in quality and durability to the "teze," a very hard and substantial wood coming from the Madagascar forests. According to the American Consul at Tamatave, there are four or five other species of mangrove trees being worked for various purposes. By the public service the mangrove wood is used for general construction and building, and for bridges; by the natives for house-building and making household utensils, such as dishes, plates, spoons, etc., and in commerce it is sold both wholesale and retail, sometimes being exported as far as India for use in boat-building. It is estimated that by working the *tsitolony* bark the present production can be continued for four or five years, when it is expected that there will be a decline for an equal number of years, after which the *anabovahatra* bark, which is said to be getting scarce, will again be in a full state of production. It takes about ten years for a mangrove tree to arrive at an exploitable stage. Mangrove trees of all kinds are worked for bark and other purposes under permits obtained from the chief of the district in which the work is to be done. Concessions may be obtained by all solvent persons approved by the Governor-General. The labourers employed in the industry are chiefly Indians, with a few Europeans and Creoles, who obtain the necessary permits and employ the natives to gather the bark. The product is controlled by a few large firms at the ports of Majunga, Nossi-Bé, and Analalava, which not only purchase nearly the entire output of bark, but furnish money to many of the workers. Practically all the bark is shipped to Hamburg in British and German ships.

THE CULTIVATION OF RICE IN SIAM.

More than forty varieties of rice are cultivated in Siam. The "hill" rice is a peculiar variety planted on the hillsides in Northern Siam, and is said to be marvellously productive. When ripe the ears of this rice are black, but when husked and boiled the grains are of a reddish colour, and have a peculiar fragrance. The "glutinous" rice is another variety, grown in the mountain valleys of Northern Siam, and forms the main food for the people of those regions, while white rice only is grown and used by the people on the plains of Lower Siam. A common kind of rice cultivated on land liable to floods during the rains, is said to grow as much as a foot in twelve hours, so that the plant often attains a height of ten feet in its efforts to keep its leaves above water. The rice commonly grown in Siam consists of the so-called light crop, which is planted on irrigated land, often as early as February, and reaped in May or June, and the heavy crop, which is planted between July and September and harvested in December and January. A prominent Siamese rice grower gives the following description of the rice supplied for export. Rice that is exported can be roughly divided into three classes—Na Muang, Pasak, and garden rice. Na Muang is the cheapest quality, and is grown chiefly in the district of Ayuthia. The grains are short and have a great deal of red rice mixed with them, and they are also very much cracked, and therefore liable to be broken in milling. Pasak rice, which is of better quality than Na Muang, comes from the Pasak River district, and is

Hosted by Google

a variety of golden rice. It is only due to the soil of this district that it is of poorer quality than the ordinary garden rice. The so-called garden rice forms the main bulk of rice that is exported, and is of the best quality. Na Muang and Pasak rice are used for mixing with it. This rice was formerly grown in the ditches of vegetable gardens, but is now grown on vast tracts of land, both by broadcast sowing and transplanting processes, so that the name garden has lost its original meaning. On account of the exhibitions of rice during the last three years, very fine varieties have been brought to the notice of cultivators. Many of the varieties exhibited are considered by experts to be among the best in the world.

ARTS AND CRAFTS.

Glass (*English and Foreign*). — Though the making of cameo glass goes back at least to the period which produced the Portland vase, it was not until the Paris Exhibition of 1900, when certain French and German craftsmen showed some very interesting and wonderful examples of this kind of work, that much had been heard about it in modern times. Since that date it has not died out, but seems to have grown more and more popular, at any rate in France. The French exhibits at recent International exhibitions have generally included a collection, sometimes a large collection, of glass treated in this way, and some very fine examples were to be seen a couple of years ago at the Brussels Exhibition. Specimens of it are habitually shown in the best Paris glass and china shops, mostly with a neat little label giving the name of the maker, and it has come to be a well-known branch of French artistic craftsmanship. Indeed, by this time it is so much in demand abroad that it is being fairly extensively imitated in a way which threatens to cheapen something which at its best is really beautiful. The work of Gallé, Daum, and others, is too well known to need description, and its method—the laborious cutting away of one or more layers of glass in places leaving a pattern standing (in a corresponding number of colours) on a ground of yet another tint—makes it necessarily expensive. The cheap version of such delicate workmanship leaves a great deal to be desired, and yet is sufficiently reminiscent of the genuine thing to bring it into disrepute. It is noticeable that the glass used in this modern Continental cameo work is mainly of a semi-opaque kind, which, although when artistically manipulated it gives beautiful colour effects, is very unpleasant both in tint and texture in the commoner versions. Moreover, wonderful as the best French cameo glass undoubtedly is, it is not pre-eminently glass-like, just as certain glass tiles, though they are plainly vitreous, give one the impression of being not quite glass. It may be this peculiar quality in the material which has prevented this kind of glass from becoming as popular in England as on the Continent; it may be simply that the British public is not prepared to pay the price which the good work demands, and will not be content with the bad. However that may be, we have seen comparatively little cameo glass in England, and until recently the English makers do not appear to have done anything with it. Now, however, Messrs. James Powell & Sons have produced a few pieces which are really fine. They differ from the Continental work in two important respects—the underneath layer of glass (that which forms the vase itself), and sometimes also the upper layers, are formed of really clear, transparent glass, and the brilliancy of this is enhanced by the addition of gold leaf applied before the shape is blown to its full size, so that it divides into tiny fragments and leaves flecks of gold on the fully-blown vase. The most interesting piece is a blue vase some ten inches high, ornamented with a pattern of small white blossoms, touched here and there with just a hint of pink. It is a really beautiful piece of work, good in shape and tastefully decorated, and the little final touch of colour is well worth the extra trouble it has involved. Some of the other examples, in which the pattern is in transparent ruby on a paler red ground, though beautiful if seen by themselves and very suggestive, are not quite so satisfying or so subtle as the white on blue. It would seem as though the results were more satisfactory when the upper coats of glass are less transparent. The pieces are very different from the French work, and the best of them have a charm and a quality which the foreign productions lack. Besides this particular new departure, Messrs. Powell & Sons are continuing and perfecting other branches of artistic glasswork. The simple Roman cutting which they began to imitate so successfully some years ago is still being used, and they are now adapting it with success to present-day uses, as a dessert-service of a quite modern type entirely decorated with this type of cutting shows. Some of the copies of old Waterford, although, of course, executed in a more usually accepted style of cutting, are also very interesting. The number of reproductions and adaptations of old vases found in Crete and elsewhere is being steadily added to, and the translation of vessels made originally by rather primitive pottery methods into glass provides an opportunity for using a thick engraved line, which forms a very effective contrast to the clear glass, and one for which there is no scope in the more everyday types of vases. Not the least of the beauties of these objects is that they are so absolutely glasslike. There is nothing, in spite of the clay prototypes which gave the first hint of some of them, to suggest any other material or to make one feel that any of them could have been executed more satisfactorily in pottery or carved stone.

Quilts and Quilting.—Heartily as certain doctors may dislike them, eiderdown quilts are nowadays almost as necessary an accompaniment of a bed as are counterpanes—or bedspreads as we are are learning to call them. The time has long passed

Hosted by Google

when it was looked upon as inevitable that these quilts should be covered with a cotton material, gaudily printed with an adaptation of an Indian or Persian pattern. It has been for years the custom to encase the down in silks or sateens of pretty and harmonious colours, sometimes plain, more often patterned, which either match or tone in with the hangings and covers of the bedroom. Various experiments, more or less successful, have also been made in combining plain and patterned stuff on the same quilt; but for the most part the value of the quilting itself as a means of obtaining pattern has been quite overlooked. This is all the more remarkable, because most people know something of what has been done in the way of quilting in the past. Those who have not wandered far from home are aware that quilting is one of the old-established industries in certain parts of this country. Those who have travelled rather farther afield are familiar with the attractive quilted coverlets (in which the stitching in another colour plays so important a part in the decoration) to be seen hanging out of countless windows any fine morning in Palermo and other towns of Southern Europe. People interested in embroidery all know the wonderful quilt illustrating the history of Tristram and Isolt in the Victoria and Albert Museum; not a thing to be copied nowadays, but a marvellous and beautiful production none the less. It is, however, only recently that manufacturers over here seem to have bethought themselves of the possibility of letting the stitching of the ordinary quilts of commerce form their decoration. They have before been content to let the necessary stitching down of the material take the form of any dull geometric pattern that came to hand. The fashion of using plain instead of patterned materials for decorative purposes has in this particular case, however, led only to the substitution of stitched for printed ornament. The custom of covering quilts with self-coloured material has, it would seem, made people notice the poverty of the plans on which the stitching is based; and this year we find quite a number of fresher and more ambitious patterns being employed. The motifs so far are not very elaborate, but they are a step towards real design, and are sometimes reminiscent of good old quilting patterns. The difference in the materials employed would preclude the production of anything resembling the most elaborate of the old work, even if it fitted in with our modern ideas, but there is no reason against, and every reason for, the introduction of good designs to take the place of lattices, panellings, and other unsatisfactory and rather makeshift plans which used to be in vogue. It is to be hoped, by the way, that the undesirable practice of outlining portions of the pattern in coarse lace, which spoils the proportion of the design and makes the whole thing look like an enlarged pin-cushion of a fussy and most untasteful kind, will not tend to divert into wrong channels something which is otherwise undoubtedly a movement in the right direction.

CORRESPONDENCE.

COLONIAL REPRESENTATIVE GOVERNMENT.

In the *Journal* of the 18th inst., the late Governor of Barbados rightly gives priority to Virginia in representative institutions, by a grant in 1619, one year before the grant to Bermuda. He adds a caution that a grant did not necessarily imply the immediate establishment of parliamentary government. Let us see what happened in Virginia. On April 19th, 1619, Sir George Yeardley (successor to Lord Delaware, deceased) arrived with a new authority under the Charter, by which the powers of the governor were limited by a council, and an annual general assembly, to be composed of the governor and council, and two burgesses from each plantation, to be freely elected by the inhabitants thereof. On July 30th, 1619, in accordance with the Governor's summons in June, the first representative legislative assembly ever held in America was convened in the chancel of the church at James Town, and was composed of twenty-two burgesses from the eleven several towns, plantations, and hundreds, styled boroughs. The proceedings were opened with prayer, and each burgess took the oath of supremacy. A speaker, a clerk, and a sergeant-at-arms were elected. The education and religious instruction of the children of the natives was enjoined upon each settlement. Tobacco was authorised as a currency. The government of ministers was prescribed according to the Church of England, and a tax of tobacco levied for their support. It was also enacted that "all persons whatsoever, upon the Sabbath days, shall frequent divine service and sermons both forenoon and afternoon."

Thus in Virginia representative institutions took effect without delay. Just a month after the meeting of the first assembly, in "August, 1619, came in a Dutch man-of-warre that sold us twenty Negars," and so began negro slavery. In the same year there were sent to the colony one hundred disorderly persons or convicts, by order of the king, to be employed as servants. Boys and girls picked up in the streets of London were also sent and bound as apprentices.

My authority is the "History of America," edited by Justin Winsor, librarian of Harvard University. The proceedings of this early assembly are not beyond criticism, but allowances must be made—they occurred a long time ago, and the Colony had not learned to prosper.

William Latham.

GENERAL NOTES.

The Salt Industry of Honduras.—Choluteca and Valle furnish most of the salt used in the interior of Southern Honduras. There are two methods of making salt—sometimes the sea-water

Hosted by Google

is used and sometimes the ground along the beach. In the first case the water is gathered in vats built in the ground, where it remains twenty days. It is then placed in earthen vessels and boiled until the process of evaporation has been completed. In some cases iron pans six feet long and wide and thirteen inches deep are used instead of the native vessels called "hoyas." After the earthen vessels have been used a number of times, a part of the salt has accumulated in the form of a hard lump, and adheres to the bottom of the vessel. This hard salt can be got out only by breaking the vessel. It is called "curuma," and is used in food for cattle. Where iron pans are used, the furnace is sometimes provided with two chimneys, and, when large enough to heat two or three pans, it has several divisions to prevent all the heat being drawn into the back part of the furnace. The water is boiled eleven hours, the salt taken out, and the process renewed. One iron pan produces 700 lbs. When the ground itself is used, a part of the beach is ploughed up with an implement having a number of prongs, and allowed to dry in the sun. It is placed in troughs made from the trunks of trees, twenty-one to twenty-four feet long, mixed with salt water, and filtered through straw into a small trough that carries the water to a second large one, several feet lower than the first. Here it is weighed to determine the amount of salt, and then evaporated as in the first method.

The Glove Industry of Grenoble.—According to the latest statistics there are about three thousand men and women employed in the glove factories of Grenoble, and about twenty thousand more work in their homes in that city and its vicinity. The yearly production of gloves is about 1,500,000 dozen pairs, valued at £1,875,000. During 1911, the necessity for counteracting foreign competition and recovering lost ground led to the establishment of a special local school of glove-making, as a section of the Vaucauson School. For a number of years the establishment of a national school of this character was under discussion, but the question of expense stood in the way. It is provided that at least ten students shall be graduated each year as experts in the fabrication of gloves, following the regular three or four years' course in this school. These students, through their knowledge of details and general commercial requirements, will be fitted to act as superintendents of glove factories, agents for the sale of gloves, or instructors of others in the same industry. The course of study will include the origin, quality, choice, handling, buying, and preservation of skins, leather dressing, assorting, tanning, dyeing, and pulling; colouring matters and chemical manipulations; cutting, sewing, hand work, machine work, embroidering, finishing, and packing; foreign markets and competition; transportation, tariffs, etc.

Opal Production in Australia.—The mines producing black opals are situated at the head of the River Darling, New South Wales, about sixty miles from the village of Walgett. They were discovered nearly nine years ago. The output for the first three or four years was very small indeed, only an occasional black stone being found, but some larger finds were subsequently made, and attracted a large number of miners, at one time a thousand or more being at the field. The black opal is confined within very small limits, and the supply has gradually fallen off, until during the last few months the output has been almost nil. Very likely the mines are not exhausted, but the discovery of the new run of stone, difficult at the best of times, will be still more difficult on account of the number of miners being so much reduced. The Australian opal production of all descriptions is now 75 per cent. less than has been known at any other time during the last twenty years, and black opal in particular has temporarily ceased to be produced. In addition to New South Wales, opals are found in the Beechworth district of Victoria, and in Queensland the opaliferous district stretches over a considerable area of the western interior of the State, from Kynuna and Opalton as far down as Cunnamulla.

MEETINGS FOR THE ENSUING WEEK.

Monday, October 28...Architectural Association, 18, Tufton-street, S.W., 7.30 p.m. Mr. L. Weaver, "Small Country Houses of To-day."

Tuesday, October 29...Sociological, at the Royal Society of Arts, John-street, Adelphi, W.C., 8.15 p.m. Dr. W. F. Mott, "Is Insanity on the Increase?"

Zoological, Regent's Park, N.W., 8.30 p.m. 1. Mr. R. Lydekker, (1) "'*Gazella hayi*' = *Gazella fuscifrons*"; (2) "The Bornean Bantin." 2. Mr. E. G. Boulenger, "Notes on the Breeding of the 'Millions' Fish (*Girardinus pœciloides*)." 3. Rev. T. R. R. Stebbing, "On the Crustacea Isopoda of the 'Porcupine' Expedition." 4. Dr. F. E. Beddard, "Contributions to the Anatomy and Systematic Arrangement of the Cestoidea.—VII. On Six Species of Tapeworms from Reptiles belonging to the Genus *Ichthyotœnia* (s. l.)." 5. Mr. E. Dukinfield Jones, "Descriptions of new Butterflies of the Genus *Thecla* from S.E. Brazil."

Wednesday, October 30...Auctioneers' and Estate Agents' Institute, 34, Russell-sq., W.C., 8 p.m. Inaugural Address by the President, Mr. Arthur W. Brackett.

East India Association, Caxton Hall, Westminster, S.W., 4.30 p.m. Mr. R. Grant Brown, "A Common Alphabet for India."

United Service Institution, Whitehall, S.W., 3 p.m. Major C. H. Richardson, "The Employment of War Dogs, with special reference to Tripoli and other recent Campaigns."

Royal Archæological, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Mr. C. H. Bothamley, "The Walled Town of Aigues Mortes."

Thursday, October 31...Child Study, 90, Buckingham Palace-road, S.W., 6.15 p.m. Address by Mrs. Fanny Fern Andrews.

7.30 p.m. Dr. F. H. Hayward, "Statistical Theory for Teacher and Administrator."

China Society, Caxton Hall, Westminster, S.W., 8.30 p.m. Mr. Oliver Bainbridge, "The Heart of China."

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. A. H. Blake, "Portugal: Land and People."

Friday, November 1...Engineers, Junior Institution of, 39, Victoria-street, S.W., 8 p.m. Mr. H. P. Philpot, "A Tramp in Switzerland."

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

OCEAN WAVES, SEA-BEACHES, AND SANDBANKS.

By Vaughan Cornish, D.Sc., F.R.G.S., F.G.S.

Lecture I.—Delivered January 22nd, 1912.

On the Height, Length, and Speed of the Highest Waves finally produced in Deep Sea by a Wind of given Velocity.

In a former paper * I examined the observations of heights of waves in the deep sea as recorded by officers of the French Navy, and showed that the average height of the waves increased proportionally to the increase in the velocity of the wind, so that velocity of wind in statute miles per hour = 2·05 × *average* height of the waves in feet; or, in other words, the average height of the waves in feet was very nearly one-half the velocity of the wind in statute miles per hour.

In a later publication † I gave particulars of the height of the waves in a limited number of storms at sea, in which the waves seemed to have attained their full development, some of the cases being my own observations, others those of observers who had sufficiently recorded the attendant circumstances of position and weather. These heights are, of course, greater than those given by the constant in the above empiric formula, but they are not inconsistent with direct proportionality to the velocity of the wind, using a higher constant, such as 0·7 instead of 0·5.

When preparing the first cited paper—that of 1904—I had examined also the lengths of waves recorded by the French observers, but found that their relation to the velocity of the wind was so variable that I abandoned for the time the attempt to obtain an empiric formula connecting the two quantities. It was apparent that although the waves soon attained, in the open sea, a height not far short of the highest possible, yet the measurements were often made while the growth of length was still far from complete. Conversely, if measurements were made soon after the wind began to decrease, the height of the waves had appreciably diminished, but their length had not.

I have since found that, by restricting the examination of figures to cases where the record of weather and position shows that the wind has had time and opportunity to complete its work, consistent results are obtained connecting the observed speed of the waves with that of the wind. In some of these cases the length of the waves has also been directly observed. The fact that waves driven by the wind have very nearly the same length as those of the same speed travelling by gravitation alone in calm weather is sufficiently established by observation to allow the length to be calculated from the observed speed in the remaining cases, and *vice versâ*. The following records by other observers are among those selected as satisfying all requirements in my book on waves, written before I had hit upon the numerical relation which is the subject of the present lecture. Their selection from among many was, therefore, quite unbiased.

Lieutenant Paris, of the French Navy, in a storm in the Southern Indian Ocean which lasted four days, observed during the first day a wave-length of 371 ft., corresponding to a speed of 30 statute miles per hour, but during the fourth day a length of 771 ft., corresponding to a speed of 43 s.m.p.h. The velocity of the wind was 46 s.m.p.h.; so that during the first day it blew across the ridges of the waves at 46 − 30 = 16 s.m.p.h., but during the last day its excess speed was only 3 s.m.p.h.—*i.e.*, the highest waves were travelling with a speed nearly equal to that

* *Geographical Journal*, May, 1904, "On the Dimensions of Deep-Sea Waves," etc.

† "Waves of the Sea and other Water Waves," by Vaughan Cornish. (Fisher Unwin, 1911.)

Hosted by Google

of the wind. Thirty waves were 29·5 ft. high, six were 37·7 ft., and some were higher than this.

In an exceptionally prolonged storm in the Southern Indian Ocean, Captain David, of the s.s. "Corinthic," recorded waves of an average length of 675 ft., with a calculated velocity, therefore, of 40 s.m.p.h., the wind being 44 s.m.p.h.—*i.e.*, with an excess velocity of only 4 s.m.p.h. The heights of the waves ranged from 38 ft. to 45 ft.

The following observations by the Honble. Ralph Abercromby are among those which I have often cited as being some of the most fully described. On the voyage between New Zealand and Cape Horn, on June 10th, 1885, the velocity of the wind was 31 s.m.p.h., rising in some squalls to 37 s.m.p.h. He measured waves of velocity 32, 35, 39·5, and 28·5 s.m.p.h., the average velocity being, therefore, 33·75 s.m.p.h. The lengths of those travelling at 32, 35, and 28·5 s.m.p.h. were measured, and found to be 507 ft., 470 ft., and 358 ft.—average 445 ft. Individul waves were measured with heights of 26 ft., 21 ft., 23·5 ft., and 26 ft., or an average of 24 ft.; but a sensitive aneroid registered a total rise and fall of 35 ft., which I explain by the supposition that there was a swell running with a height of 11 ft. Thus the velocity of the high waves was not less than the average velocity of the wind.

In a storm in the Bay of Biscay on December 21st, 1911, I had the opportunity of seeing large waves in final and regular development. They were produced by a wind which happened to have precisely the same direction as a regular and heavy swell which was already running. The waves rapidly increased in height, speed, and length, until we enjoyed the unusual spectacle of perfectly regular storm-waves with no "swell," no noticeable minor waves, and no crossing of wave-crests. The ship—P. & O. s.s. "Egypt"—was hove-to at about 3.30 A.M., and rode out this storm until about 1 P.M. I observed the waves from 8 A.M. until 1 P.M., both from the promenade deck with an eye-height of 27 ft., and from the captain's bridge with an eye-height of 54 ft. The sun was shining and the weather clear, and every circumstance combined to make observations unusually easy and satisfactory. The ship being held stationary, head on to the waves, the real and the apparent speed of the waves were the same, and the ship's length gave a base of measurement for the distance between two crests viewed simultaneously from the bridge without correction for difference of direction. The ship's length gave the base for calculating the speed from the time of traversing the distance from stem to stern as seen from the bridge, also without correction. This time, combined with the period, gave a second mode of observation of the length.

The period gave also a means of comparing the calculated length with the observed length of a wave. These measurements were made at noon. The agreement is sufficiently good to give me confidence in deducing the length of the waves at 10 A.M. and 8 P.M. from the period then observed. The velocities of the wind are obtained by taking the mean of two sets of estimations :—

	Beaufort's number.		Velocity s.m.p.h.
Wind at 4 a.m. . .	9	10	48·5
„ 8 a.m. . .	9	9/10	46·5
„ noon . . .	8/7	8	35·5

The waves observed were :—

Time.	Period observed.	Length calculated from period.	Length observed by simultaneous crests.	Length observed indirectly.	Speed observed in s.m.p.h.	Speed calculated from period in s.m.p.h.
	Seconds	Feet	Feet	Feet		
8 a.m. . .	13·5	933	—	—	—	47·15
10 a.m. .	12·5	821	—	—	—	43·66
12.15 p.m..	11·27	651	612	708	42·74	39·37

[The above calculations are performed with the precise factors used in the General Formula (see *post*). The figures quoted from my book on "Waves of the Sea" are calculated by a somewhat rougher approximation.]

At 10 A.M., with an eye-height of 27 ft., almost every wave passed considerably above my line of sight, and I estimated this excess of height at 4 ft., which would make them 31 ft. in height. There was a remarkable approach to uniformity in height, the sea differing in this respect from that in which there is a swell running at the same time as the shorter storm-waves. Being occupied with measurements of length and speed, I had not time to make a detailed examination of the heights by seeking different elevations on the ship which would

Hosted by Google

place me on a level with the lowest and the highest waves. Judging, however, from the general appearance, coupled with the experience of measurements on former occasions, I should say that there were few waves which differed by more than 5 ft. from the average, which would make the range of height, except in isolated instances, only about one-third of the mean, viz., from 26 ft. to 36 ft.

The above observations show that the highest series of waves—which, indeed, was the only series visible—were travelling at a speed almost if not quite as great as that of the wind by which they were produced.

So much for the speed of the highest waves I have observed at sea during storms. I proceed to describe observations of the period—and, by theoretical calculation, the speed—of the waves which reach the seashore as breakers.

On December 29th, 1898, I observed at Branksome Chine, on the Dorset coast, between Bournemouth and Poole, 139 consecutive breakers with an average period of 19 seconds, and therefore a calculated velocity when in deep water of 66·5 statute miles per hour and a deep-water wave-length of 1,850 ft. There were very strong winds on the Atlantic from December 25th to 29th, 11–12 of Beaufort's scale (64–77 s.m.p.h.) being recorded on ships. On land, 77 s.m.p.h. was recorded at Alnwick, Northumberland, at 10 P.M. on the 27th, and 71 s.m.p.h. at 2 A.M. on the 28th. Waves 45 ft. to 52 ft. high were reported in N. 47° W. 19° on December 29th from s.s. "St. Simon," but I have no details as to how the heights were estimated.

On February 1st, 1899, I observed twelve consecutive breakers at Branksome Chine with an average period of 22·5 seconds, which is the longest period I have ever observed. Their calculated speed in deep water is 78·75 s.m.p.h., and their wave-length 2,594 ft. Owing to the exceptional violence of the winds during this season the Meteorological Office collected all available data of weather in the North Atlantic, and published an atlas showing the size and position of the depressions and the direction and strength of the winds. It shows nothing on January 31st or February 1st to account for the swell observed at Branksome Chine on February 1st; but on January 30th there was a solitary deep depression with wind a little S. of W. of force 11–12—*i.e.*, velocity 64–77 s.m.p.h. From the actual situation of the depression this direction is true for the entrance to the English Channel. In order that the waves should reach Branksome Chine at the time of my observation they would have to advance at a speed of 40·8 s.m.p.h.

The waves which I observed travelling individually at 78·5 s.m.p.h. would advance *as a group* at half this speed, viz., 39·75 s.m.p.h. As no wind force 11–12 was recorded at sea on January 31st and February 1st, the height of the individual waves would not be maintained by the wind, and the front member of the group would continually be dying out, to be replaced by a new member in the rear; so that it is the group velocity, and not the individual velocity, which has to be calculated in tracking these waves to their source.

There is considerable probability, therefore, that the waves with an individual velocity of 78·5 s.m.p.h., which I observed at Branksome Chine, were produced by wind of velocity 64–77 s.m.p.h. at 2,000 miles; that is to say, 4,000 wave-lengths distance.

The question of the time during which these high velocities of wind were maintained must also be considered. During this stormy season an average velocity of 53 s.m.p.h. (Beaufort's 10) was maintained, as observed on land, for six hours on January 12th, 1899, and 70–76 s.m.p.h. for one hour.* During the same month a velocity of 80 to 90 s.m.p.h. was attained by gusts of wind.† The highest recorded velocity in any gust of wind of which I have knowledge is 103 s.m.p.h.

Thus the greatest velocity of waves calculated from the longest periods of breakers which I have observed is practically equal to the speed of the wind as indicated by the highest logged numbers at sea, and the highest average velocity of wind maintained for one hour on land during the same season. I should add that the group of twelve breakers of 22·5 seconds period were of not inconsiderable size, considering the somewhat sheltered situation in which they were observed, and the group of 19 seconds period (66·5 s.m.p.h.) were unusually large. Thus the observations indicate, first, that waves travelling as fast as the average velocity of the strongest winds form large breakers upon the shore; and, secondly, that, if there be swifter waves produced directly or indirectly by the action of wind upon the sea, they do not attain sufficient height to form noticeable breakers.

Combining the results of the observations at sea with those from the shore, I consider that I am now in a position to propose a settlement

* F. J. Brodie, *Quarterly Journal of the Royal Meteorological Society*, 1902.

† *Symond's Meteorological Magazine*, May, 1900.

Hosted by Google

of the long-debated question of a formula which shall express the connection between the speed of the wind and the dimensions of the highest waves which it produces in deep sea far from land. As already stated, the records of average height in feet observed at sea are approximately equal to half the velocity of the wind in statute miles per hour. For those occasions on which the wind has had as full opportunity as it ever enjoys of doing its work, direct proportionality still holds good, but the constant is higher. I find that seven-tenths best satisfies the available observations between a strong breeze and a whole gale. The same simple proportion would not hold if we began with the heights corresponding to the gentlest breezes, which would probably rise in a steepening curve; but the only part of the line which is of nautical importance is that part which comprises waves of considerable size, and this part is a straight line.

My chief difficulty in obtaining a general formula has hitherto been the determination of the relation between wave-length and velocity of the wind. Having now, however, found that the highest waves finally formed are those travelling at a velocity which is equal, within the errors of observation, to that of the wind, their length can be directly calculated from the observed velocity of wind. I thus obtain the table given on page 1109, which shows the height and length, and, therefore, also the steepness, of the highest waves finally produced in deep sea far from sheltering land by winds of the different velocities corresponding to the numbers from six to twelve—strong breeze to hurricane—on Beaufort's table of wind force.

It will be noticed that, since I find the velocity of the waves to be equal to that of the wind, their length, according to the theory of waves, is proportional to the square of the velocity of the wind. Now I find the height to be proportional to the velocity of the wind. The height divided by the length—that is to say, the steepness—of the waves is, therefore, inversely proportional to the velocity of the wind. The table gives the steepness of the highest waves formed by wind of any velocity, but the waves are steeper before they acquire their final speed and greatest height.

In the table two constants depend upon observations, viz., the equality of velocity of wave and velocity of wind, and the factor 0·7 for converting velocity of wind in statute miles per hour to height of wave in feet. The other factors employed are given by the theory of trochoidal waves travelling in deep water.

General Formula for calculating the length and height of the waves finally produced in the open sea by the action of winds of any velocity from 25 to 77 statute miles per hour.

This formula is based upon—(1) The observation that in prolonged storms, or when the wind blows directly upon a swell of less than its own speed, the waves travel with the same speed as the wind, within the limits of the errors of observation. (2) The observation that the breakers of longest period have a calculated deep-water velocity equal to the maximum average velocity of wind recorded for the same spell of weather. (3) The observation of heights of fully-developed waves at sea. (4) The relation between speed, period, and length of waves given by the theory of trochoidal deep-water waves; employing the formula — speed of wave in feet per second $= 5\cdot123 \times$ period $= \sqrt{5\cdot123 \times \text{length}}$ (*vide* Chapter V. of Sir Wm. H. White's "Naval Architecture"), and converting from feet per second into statute miles per hour by use of the factor 0·6818.

Description of Wind.	Beaufort's number for wind-force.	Velocity of wind (V) in statute miles per hour = Velocity of wave.	Period in seconds = V ÷ 3·493.	Length in feet = V² ÷ 2·382.	Height in feet = V × 0·7.	Length ÷ Height = V × 0·600.
Strong breeze .	6	25	7·2	262	17·5	15·0
Moderate gale.	7	31	8·9	404	21·7	18·6
Fresh gale. .	8	37	10·6	575	25·9	22·2
Strong gale .	9	44	12·6	813	30·8	26·4
Whole gale .	10	53	15·2	1180	37·1	31·8
Storm . . .	11	64	18·3	1720	44·8	38·4
Hurricane .	12	77	22·0	2489	—	—

Note on the Height of Waves.—The figures are for the average waves. When their speed is equal to that of the wind, there is not the great variation in height which occurs when the wind has a velocity less than that of the swell left by a preceding storm and occasional high waves are formed by superposition.

Note on the Length of Waves.—When the length is judged by the apparent distance which separates two wave-crests viewed simultaneously, the result is generally much less than the true length. Unless special precautions are taken, the eye is completely deceived. Reliable

results are obtained by determining the time occupied by the waves in running the length of the ship combined with the interval of time between the arrival of the waves. This mode of measurement is, of course, independent of the theory of the relation between period and length.

Note on "*Force* 12."—A short group of breakers of the corresponding period have been observed by the author; but there is no reliable record of a sea in which the height of the waves averaged 53·9 feet, presumably on account of the extreme force of wind not being long maintained. Breakers corresponding in period to force 11 have been recorded in a long series.

I anticipate that seamen will object that the wave-lengths given in the table exceed their experience of the apparent length of waves. I have pointed out elsewhere* that although there is agreement between the records of systematic observation of heights of waves and the experience of navigating officers, there is a discrepancy in the matter of wave-lengths. Wave-length in the case of systematic observations has generally been determined indirectly by noting the time occupied by a wave-crest in running the length of the ship and the interval of time between the arrival of successive waves. The result is to give wave-lengths much greater than those generally assigned by officers on the bridge who notice the apparent distance between contiguous wave-crests viewed simultaneously. Only in the case of very long and regular waves, such as those seen in westerly storms in the Southern Ocean, is there an approach to concordance. For ordinary rough weather in the North Atlantic the discrepancy is about 100 per cent., the general estimate of seamen being about one-half that obtained by systematic observation of succeeding waves. Observing from the promenade deck of passenger steamers, I found that my estimate of the apparent length of waves viewed simultaneously agreed, on the whole with that of the navigating officers, and was much less than that calculated by theory from my observation of the periods. It was only on my voyage in December, 1911 (Marseilles to Plymouth by P. & O. s.s. "Egypt"), that I was able to satisfy myself as to where the truth lay. On December 19th, off the coast of Portugal, there was a heavy swell occasionally rising to more than 20 ft., and with a period of about 11 seconds. I came to the conclusion that when judging the distance between crests of succeeding waves along the ship's side my eye had in the past been deceived owing to the steep slope at the shoulder and the almost flat top of the waves. I decided that I had taken points a little beyond the *shoulders* of the receding and advancing waves as their summits, and thus systematically underestimated the wave-length by a large amount. Two days afterwards I had an opportunity of testing the matter, and convinced myself that the appearance which had so long deceived me commonly deceives even the practised eye of the seaman. When on the passenger deck of the s.s. "Egypt" at 9 A.M. of December 21st, the day of the storm already referred to, I was unable to satisfy myself whether the waves were or were not as long as the ship—512 ft. I had not the opportunity of obtaining at the moment the opinion of a navigating officer, but one of the engineer officers was good enough to address himself to the subject. He judged the length of the waves to be about 200 ft. As we were hove-to head to wind, the conditions were favourable to observation. Going on to the navigating bridge, I had from this position of vantage no difficulty in deciding that the large and regular waves were longer than the ship, for the stern was on one crest when the next crest had not yet arrived at the dipping bow. I estimated the wave-length at 100 ft. longer than the ship, and this estimate was approximately confirmed by the indirect measurement of length, and both were in fair agreement with the length theoretically calculated from the period. A navigating officer who co-operated with me in observing the same waves as they took the ship within their length, estimated their length at 542 ft. as against my 612 ft.; but another navigating officer on the bridge, who had been noticing the sea but not joining me in my systematic observations, judged the length of the waves to be 180 ft. The observations given in the table prove beyond reasonable doubt that the waves were quite 600 ft. long. At the time when the engineer officer from the passenger's deck estimated the waves at 200 ft. the observation of period gives their theoretical length at 800 ft., and my observations on the bridge proved that the lengths calculated from period were the actual lengths.

I do not think, therefore, that there is any longer room for doubt that, unless special precautions be taken or the circumstances be specially advantageous, the eye is completely deceived in judging the length of waves from the apparent distance between contiguous crests viewed from on board ship. Error is least when the eye is high above the waves.

AUSTRALIAN MANUFACTURES.

The present rush of emigrants to Australia calls attention to the remarkable development of the Commonwealth during the last fifty years, and especially to the expansion of home manufactures. The days when the wealth of Australia was represented only by mines and sheepruns are long past, and the quantity and variety of goods exported give proof of the expansion of the resources of the country. A limited number of statistics respecting these industries are to hand, and from these we propose to quote in this short article.

The term "factory" is used throughout the Commonwealth to indicate any workshop, mill, or factory where more than four persons are employed. Annual conferences of statisticians have supplied valuable data, but the results are not totally satisfactory, as some States do not collect statistics with as much method as others.

The following table gives the latest annual report of the total value of the output of factories in the Commonwealth. It is taken from the last edition of the official Year Book of the Commonwealth of Australia:—

In this table the articles have been arranged according to their individual monetary value for the convenience of the reader, rather than under class headings. Under "Food and Drink" twenty-one different kinds of manufacture are reported. These include bacon-curing and the preparation of other dairy produce, confectionery, canning and preserving, ice and refrigerating, sugar mills and refineries, breweries and aerated waters. Over two and a half million sheep are treated every year, besides vast quantities of hares, rabbits, and poultry.

Jam-making and fruit preserving have largely increased with the development of orchards and fruit-growing. The industry is young as yet, but is capable of considerable expansion. During the last ten years confectionery and biscuit-making have also greatly expanded.

Large refrigerating works have been installed in various parts of Australia. The export of mutton and lamb preserved by the cold process now amounts to £1,200,000 a year. Much attention is paid to breeding in all the States.

Sugar-milling began in Australia long before sugar-refining. The raw material used was brought from Mauritius and the East. Several

Total Value of Output of Factories in Commonwealth, 1909.

1	Food and drink	£38,337,097
2	Metal works and machinery	19,692,545
3	Clothing and textile fabrics	12,572,309
4	Treating raw material product of agricultural and pastoral pursuits	9,258,911
5	Working in wood	6,344,019
6	Books, paper, printing, and engraving	5,299,607
7	Heat, light, and power	3,362,428
8	Vehicles and fittings; saddlery and harness	2,375,974
9	Processes in stone, clay, and glass	2,118,605
10	Drugs, chemicals, and by-products	2,089,747
11	Furniture, bedding, and upholstery	1,836,311
12	Treating oils and fats (animal and vegetable)	1,635,063
13	Minor wares	814,147
14	Jewellery, timepieces, and plated ware	534,804
15	Ship and boat building and repairing	479,646
16	Leatherware	352,890
17	Musical instruments, etc.	141,304
18	Arms and explosives	122,361
19	Surgical and other scientific instruments	41,965

Hosted by Google

small home mills have been closed owing to the preference for cane-crushing in mills with modern machinery. On the north coast of New South Wales certain land formerly devoted to sugar growing has been turned into pastures and used for dairy purposes.

The trade in Australian wines is growing steadily as the excellent qualities of the vintage become known in other countries. In addition to grapes for wine-making, large quantities are grown for table use and for drying. A considerable amount of fresh fruit is exported.

The metal works include agricultural implements, cutlery, engineering, ironworks and foundries, railway carriages, lead mills, railway and tramway workshops, wire-working and other metal works. Many of the tramways are owned by private companies; the electric tramways of Brisbane, for instance, have an office in London. Hundreds of miles of tramways are used for special purposes, such as those employed in the sugar-milling industry for hauling cane to the mills. In each State railways are under the control of the Government, except in cases presenting unusual circumstances.

There are now a considerable number of large and important engineering works which engage in the manufacture of special classes of machinery and implements, besides those which provide for local domestic requirements. The manufacture of agricultural implements is very important, and is of special interest, as it is one of the first industries to which an attempt was made to apply the "New Protection" system, as it is called. Amongst machines made the "stripper-harvester," which combines the stripper with a mechanism for winnowing and bagging grain, is an Australian invention, and is exported to many countries.

The clothing made in the Commonwealth includes excellent home-made tweeds, flannels and blankets, of which the hard-wearing qualities are valued. There is no cotton-spinning or weaving or linen-weaving carried on in Australia. There has been cotton-ginning from time to time, and a mill was lately reopened at Ipswich in Queensland. Hat and cap-making, and the manufacture of boots and shoes, are also flourishing industries.

Details with regard to vessels built in the Commonwealth are somewhat meagre. Twenty-nine steam vessels and twenty-three sailing vessels were built and registered in 1909.

The trade in hides forms a considerable export. Between the years 1905–9 no less a sum than £9,071,345, or an average of £1,814,269 per annum, was represented. The largest item included arises from the sheepskins with wool, which are shipped chiefly to France and the United Kingdom. The quantity of wool alone sent from the Commonwealth between 1905–9 amounted to £119,757,161 in value. The value of Australian wool imported into the United Kingdom in one year is £13,668,466.

There are between three and four hundred factories engaged in furniture and cabinet-making and billiard-table making in Australia. The total value of the annual output when the last statistics were collected was £1,193,308.

It has not been possible to obtain satisfactory information concerning wages in all parts of Australia. The rates in many industries vary considerably in different parts of the country. Then again, the necessary particulars are not collected by the several States on a uniform basis; while for some States the information given is meagre and unsatisfactory. The highest amount paid in salaries is in metal works and machinery—£5,194,376. The clothing and textile fabrics industry comes next with a wage list of £3,599,178. The minimum amount is in the surgical and scientific instrument trade. The State in which the largest amount of salaries is paid is New South Wales, which totals £7,665,125, or nearly ten times as much as is paid in Tasmania.

The average amount of wages paid per employee in 1909 was £87·27 in New South Wales, £73·57 in Victoria, £82·09 in Queensland, £83·08 in South Australia, £122·21 in Western Australia, £87·78 in Tasmania, £83·01 in the Commonwealth.

Women are employed in increasing numbers in Australian factories. The number of women to 100 men is about 35·76, as against 32·78 eight years ago. The increasing percentage is due to the activity of the trades in which women are usually engaged rather than to the substitution of female for male labour. Large numbers are occupied in tailoring and dressmaking, in wholesale manufactures, in tobacco factories and preserving works.

The employment of children is mainly confined to a limited number of industries, the most important being paper-making, dressmaking and millinery, and clothing. In New South Wales no child may be apprenticed under the age of fourteen years; in Victoria and Queensland, twelve years. There is no limitation in the case of other States, nor any regulating Acts, except as applying to charity apprentices.

URANIUM: ITS DISCOVERY, CHEMICAL COMPOSITION AND USES.

The metal uranium is somewhat sparingly distributed over the surface of the earth, principally in the mineral pitchblende, which consists almost entirely of oxygen and uranium (other rare metals in a more or less degree are associated with pitchblende).

Pitchblende, a dark mineral named from its characteristic fracture very similar in shape and colour to that of hard pitch, is interesting as being the mineral in which uranium was first discovered, and which contains, so far as at present known, the greatest amount of radium of all the minerals; whilst the species called chalcolite, uranite, and

Hosted by Google

the various other compounds are recognisable by their brilliant colours of green and yellow crystals.

Uranium was discovered in 1789 by the German chemist Klaproth, and the metal was first isolated by Peligot, the substance originally supposed to be the metal having been proved by him to be the protoxide.

The metal is obtained by several processes, the most simple being by heating the protochloride with potassium. The metal uranium thus obtained is of a white colour, and to a certain extent malleable; if heated in the air it burns brilliantly, like magnesium.

The protoxide is made by heating the oxalate of uranium in a current of hydrogen in closed vessels. It is a black powder which takes fire spontaneously on exposure to the air. It was formerly supposed to be the metal. In its anhydrous state it is insoluble in acids, but as a hydrate precipitated from its salts by ammonia it is readily soluble, forming numerous salts of an interesting character.

The nitrate is the source from which most of the compounds of uranium are procured. It is prepared from pitchblende by solution in nitric acid, the lead, arsenic, iron, and other metals and impurities, being extracted by well-known means. It forms fine yellow crystals with a peculiar green bloom running through them.

The nitrate has been used as a photographic material. The oxide has been employed in giving glass a peculiar greenish yellow fluorescent appearance of great beauty.

In the manufacture of the more expensive "Bohemian glass," uranium has played an important part. At the dinner-tables of many old families in England there are used wine-glasses and ornaments in the manufacture of which, through the use of uranium, radium to a certain extent entered. Always a rather costly kind of ware, it will now be more prized than ever. There are other salts of uranium than those already described which are very interesting to the chemist, from their anomalous composition and behaviour with re-agents, but it is not our province to describe them here. Uranium and its compounds emit peculiar rays—"uranium rays" —which can penetrate thin metallic screens and coins; these rays undergo reflection, refraction, and polarisation, and discharge electrified bodies.

Professor Henri Becquerel, in experimenting with uranium, concluded that it had the power of absorbing the sun's rays, which after exposure to the sun would cause an action on a photographic plate. It occurred to him that possibly a similar result might be obtained with pitchblende, and he discovered that this substance gave off rays of emanation which produced photographic images in the dark. It was this discovery of what is known as the "Becquerel uranium rays" in emitting radiation, which not only acted upon photographic plates, but had the power to penetrate solid substances exactly after the fashion of Röntgen rays, that led the Curies to follow out this discovery made by Becquerel respecting the rays of uranium; and when Madame Curie found that pitchblende was more than four times more radio-active than the separated uranium salts, it occurred to her to test the radio-activity of the residue after removing the salts from the pitchblende. Following out her investigations, she discovered that the radio-activity of the residue from the separated uranium was far greater than that of the pitchblende. Her husband now joined her in further investigations, in which they obtained a substance so powerfully radio-active that they proceeded to isolate the element, and they produced the chloride and bromide of radium in a state of purity sufficient to determine its essential properties.

Previous to this discovery by the Curies, the use of uranium was practically confined to use in porcelain painting, in the manufacture of glass, and in photography.

Although from the time of its discovery by Klaproth uranium has always commanded a high price, yet, owing to the comparatively small field in which it could be employed, the output of uranium ores was necessarily limited in order to maintain the market. The sources also of its supply have not been plentiful; but now search is being made in different parts of the world, particularly in Cornwall, for pitchblende, which, in order to procure radium, must be had at whatever cost.

The manufacture of radium from pitchblende does not interfere with the simultaneous production of uranium oxide, and, having regard to the large quantity of pitchblende necessary to produce a very small quantity of radium, it should follow that the supply of uranium will be greatly increased. This increase in the supply will tend to reduce the market price, and by so doing would encourage a demand for its practical employment.

As an illustration, it may be stated that uranium is one of the best-known conductors of electricity extant, and a reduction in price would inevitably increase its use in electrical construction.

Uranium mixed with steel is said to form an alloy of high quality, so that when its supply can be maintained in regular quantities, it would obviously be utilised in the manufacture of ordnance, for fine sword steel, and for other purposes of a similar character.

Bohemia can boast of the oldest uranium mine in the world, viz., Isachmisthal, which is situated on the Bohemian side of the Erzgebirge, in a very striking pass in the ore mountains. This mine has been very rich in silver; it is said to be one of the oldest in Europe, and the first for which mining laws were framed. It was from this mine that Klaproth is said to have procured the ores of pitchblende from which he discovered uranium.

It is near this mine on the southern slope of the mountains that uranium has played such an important part in the manufacture of the most

Hosted by Google

expensive Bohemian glass. Other uranium mines of note are in the German Empire, in Saxony and Cornwall. Some fine specimens of the calco-uranite have also been obtained from St. Symphorni and a few other places, including the Black Hills of South Dakota.

The ores of uranium have long been known to exist in Cornwall, but previous to the discovery of a true fissure vein of uranium in South Terras Mine, near Grampound Road, had only occasionally been met with in pockets mixed with other minerals. In Huel Providence and Trenwith, St. Ives, it was mingled with the copper ore in places in quantity sufficient to diminish its value.

At Wheal Edward in St. Just rich pockets of pitchblende were met with, and the ore collected was sold at about £200 per ton. At East Pool, between Camborne and Redruth, have been found occasionally rich pockets of pitchblende. Specimens of all the varieties of uranium have been procured at Carharrack, Huel Garland, Tolcarn, Huel Unity, and Ting Tang in Gwennap, also from the following mining districts: Gwinear, St. Agnes, St. Austell, St. Stephens, near Grampound Road, and Calstock.

Although, as previously stated, "pockets" containing the ores of uranium were met with occasionally in several places in Cornwall, it was not until 1878 that it could be said that uranium mining in that county was of any industrial value. Up to that period small quantities had from time to time been selected and sold; since then, through the discovery of a true fissure vein of uranium in the South Terras Mine by the writer of this article, large consignments of the ores have been made.

This mine, including Blencowe to the west, which receives the uranium lode in depth, is very interesting, not only on account of its valuable products, but also in respect of the enclosing rocks in which this vein is embedded. The most extensive deposits of magnetite or magnetic iron ore in Cornwall are found, enclosed within a mass of trappean rock, in places predominated by beautiful dark green and black flaky crystals of hornblende, garnet-rock, extensive beds of steatite, etc. Most of the meteoric metals are found here. Near the base of these eruptive rocks and crossing them in a northerly direction, with an inclination westward, is the uranium lode or vein.

J. H. Harris-James.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

Artificial Waste Silk.—The objective of manufacturers of chemical silk has been hitherto the production of continuous filaments, such as are reeled in long lengths from the cocoon. The direction is an eminently natural one to take, as they thereby imitate silk in its dearest form by the means which must probably be always the cheapest method to adopt. The filaments made by solidifying streams of jelly squirted through the orifices of a rose, have to support their own weight and some strain in combining them together to form a merchantable yarn. Thus a limit is set to their tenuity, and in the present state of advance the individual constituents of an artificial silk yarn are coarser, and hence fewer, than in a real silk of the same diameter. In view of certain purposes, this constitutes a severe disadvantage. It may be hazarded that one reason why artificial silk spreads, or covers, less well than natural silk in weaving is that there are fewer fibres within it. Patently, when woven with an erect pile of cut loops it is impossible that a yarn composed of few and coarse filaments should create so rich an effect as one with many more fine points. Partly for this reason, the artificial silks generally known do not lend themselves satisfactorily to making velvet. There thus emerges a practical question of how the fineness of the ultimate constituents may be reduced. The inventors of what is called "new schappe" yarn have proceeded by abolishing the continuity of length. Instead of making indefinitely long fibre, they produce short fibres of a definite length, corresponding to those recovered from waste silk by the silk dresser, and by him made upon spinning machinery into spun yarn. These "drafts"—to give them the name applied to natural silk—are some six times finer than the fibres that can conveniently be employed in making chemical silk by the older methods. For the first time we are faced with commercial proposals to manufacture artificial waste silk, and a varied collection of samples of mixed and pure "new schappe" goods is on private exhibition in Paris. According to the statements of interested parties, the drafts could be produced at 7½*d.* per lb., on the scale of one ton per day, or at fractionally over 1*s.* 2*d.* on a smaller scale. As either of these prices is less than the net labour cost of converting silk waste into drafts, the competition might seem serious. Commercially, much depends on the subsequent cost of turning the drafts into yarn, and the price that yarn commands. There has at least been a technical advance sufficient to attract the serious attention of one of the largest Lancashire firms. The new material is said to take dye perfectly, and to be capable of modification under finishing treatments.

Textile Combines.—The closing years of the last century were the halcyon days of company promotion in the British textile industry, and nearly all the combines belong to that date. The successful floating of the J. & P. Coats combination in 1896 led easily to the English Sewing Cotton Company of 1897, the Fine Cotton Spinners' and Bradford Dyers' Association of 1898, and the Calico Printers' and Yorkshire Woolcombers' Associations of 1899. These were succeeded in 1900 by a fleet of seven new combinations, with the Bleachers' Association as chief. Schemes for other and larger undertakings were in the air, but in 1901 public confidence in the magic of combination met

Hosted by Google

a violent death. The enthusiasm of the old century has never been recaptured, and with painful clearness it is seen that different combinations meet with very unequal fates. Vendors, in larger numbers than one might expect, have had time to rue the sale of their family businesses, managers have had cause to repent of numbers of their purchases, and investors' heads have been thoroughly cooled. It is not on English but Belgian and French initiative that new combines are being formed out of Lancashire spinning and weaving mills. According to inspired rumour, properties capitalised at £3½ millions are to be floated before Christmas. If low first costs are wanted, this is not a signally opportune time to buy, as current financial results are good enough to cause owners to hold tight to their mills. Neither is this an advantageous time to build if looms and materials have to be contracted for at current prices. The cotton-weaving trade is in one of its periodical bursts of expansion, with 5,000 new looms under installation in Blackburn, 3,500 in Burnley, and 1,000 in Nelson. For the most part these represent purchases made some while ago, and they do not constitute the whole extension during this year. As last year saw over 17,000 new cotton looms added in Lancashire, the leeway between spindles and looms is being caught up at a good rate. Machines cry for work in dull times as well as in good, and competition is intensified by their number. The usual hints as to economies are thrown out in connection with the new combines, but the possible savings on normal practice are remarkably restricted in the cotton trade. It is a commonplace to say that no well-established concern in the spinning or weaving industries has not realised the extreme advantage of carrying a light load of capital obligations. The success of cotton mills can almost be measured by the extent to which the capital values have been written off in the books, and their fortune alternates between short periods of excellently profitable times and long periods of dull trade.

War Influences.—A European war made the fortunes of the West Riding forty years ago, and "Franco-Prussian profits" might fitly be carved in the stonework of scores of warehouses and mansions surviving to-day. Manufacturers not accustomed to make thousands a year made thousands a month for a short while without overtaxing their ability. To be able to manufacture and deliver woollens or worsteds at all was enough to secure high prices during the disablement of Continental competition. Civil war in America closed half the mills in Lancashire, brought one quarter of the operatives to beggary, and cost Lancashire trade some £70 millions. More recently, a war in which Britain was not engaged, induced a feverish demand for woollen khaki and army blankets for Japan. The South African War had its industrial compensations, but none is imminent from the Balkan fighting. Yorkshire supplied Turkey with great quantities of khaki and grey overcoating two or three years ago, but since then the Turkish Government and private mills have entered the woollen army cloth business. Turkish summer uniforms are largely made of light, cheap Italian cotton-drill. Bulgaria and Servia both have mills to make army woollens, although there is no more certainty that these will be able to work than that supplies could be paid for or carried from this country. The Ottoman Empire, comprising Asiatic as well as European Turkey, is the third in importance of the markets for British cotton goods, and for the time being the business is thoroughly dislocated. The same is the case with the less important trade in heavy woollens done with Turkey. The regular supplies to the countries of the Allies are of less direct importance, as their business falls largely to manufacturers in their own and the neighbouring countries. Indirectly, the British textile industry is in a position to feel every shock. If those who supply the Near East consume less yarn our spinners feel it. If credit contracts so that Continental manufacturers are not disposed to buy raw materials as heavily, or at as high prices as hitherto, the effects exert their influence here in a fall of price. Uncertainty has many doors by which to enter from such a situation as prevails in the Levant, and the restraint on free dealing is a great deal more evident than any encouragement that can conceivably be lent to textile business.

Cotton-baling.—When an American judge stigmatised the American cotton bale as "a dirty, damaged, disreputable, water-soaked, wasteful, slovenly, clumsy, highly-inflammable, turtle-backed package," it was generally felt that language could go no further and that measures of reform would have to ensue. Six years of hearty accordance with this anathematisation leave the bale unaffected. The reasons for its lamentable condition are rather better understood, and tentative recommendations for its improvement have recently been made by a Washington official. The raw cotton is sent from the farm to the ginnery to be stripped from the seed and be packed in ginners' bales of a superfluously heavy and wretchedly inferior canvas. The bale weighs roughly 500 lbs., and conveys 19 to 24 lbs. of bagging and hoops. Gin presses in America are inefficient, and before export the bale has to be reduced in size to economise freight. For this purpose it is sent to a compress, owned, like the bagging factories, by a trust. Export cotton is sold on a contract known as the "c.i.f. and six," descending from the days of lighter cotton bales, and sanctioning a tare of 6 per cent. (30 lbs.). The ginnery tare of an average 22 lbs. is excessively heavy to begin with, but in order that the shipper shall not lose any weight, the weight of packing is bloated to the full 30 lbs. or beyond at the compress to the shipper's orders. The rules do not admit of the adding of more than a specified number of hoops, or the difference might be made up in steel.

Accordingly there are sewn to the bale a number of patches of second-hand bagging proportionate to the circumstances, and cotton shippers take frankly into calculation their profit on patching. The Egyptian bale, weighing 720 lbs. net, arrives in immeasurably better condition than the American, with a 3 per cent. tare, and the Indian bale is efficiently protected by a 2 per cent. tare. Under the joint influence of superannuated contract rules, the poverty of planters and ginners, the interests of middlemen and trusts, and the force of old custom, this inefficiency survives. Sea freight at some fifteenpence per 100 lbs. is paid on thousands of tons of ragged jute, whose only service is a pernicious one. Bales are needlessly damaged by water or destroyed by fire because the packing is inefficient. The cotton is soiled, and carelessness in its handling is stimulated by the force of bad example. No similarly valuable produce is so scandalously mishandled, yet nothing more tangible than a suggestion to change the export contract is forthcoming officially from America. The proposal is that a conference should be called representing the whole cotton-using world to determine on some such measure as the curtailment of the 6 per cent. tare to five per cent. There are potentialities of good in this mild palliative measure, but where so much is wrong consumers may excusably feel that their assent should be conditional upon some promise of spontaneous improvement in baling conditions.

CORRESPONDENCE.

COLONIAL REPRESENTATIVE GOVERNMENT.

I have read Mr. Latham's contribution with great interest. No doubt Virginia took advantage of her opportunities earlier than Barbados, but there was a proviso in the grant to Lord Carlisle which enabled him to play the role of autocrat for a considerable period. It must be remembered that his Charter gave him control of the whole of the Caribbee Islands, twenty-three of which are enumerated, and these include the present Windward and Leeward Islands, as well as Martinique, "Guardaloup," "Marygalanta," etc., and it is no wonder that the following was added to the grant: "And because in the government of so great a Province, oftentimes sudden occasions do fall out, to which it shall be needful to apply a remedy, before the free inhabitants of the said Province can be called; and for that it shall not always be needful in such cases that all the people be called together, therefore for the better government of the said Province We Will and Ordain, and by these presents for Us our Heirs and Successors, have granted to the said James Earl of Carlisle and his heirs by himself or his Magistrates and Officers in that behalf lawfully preferred, may make decrees and Ordinances both fit and profitable from time to time..."

So far as I have been able to discover, the first assembly was called after the arrival of Francis Lord Willoughby in May, 1650, and met on November 4th, 1651. The Governor appears to have been busy for some months resisting the fleet sent by Cromwell to reduce the islanders to submission, but they remained loyal to the King, and the meeting was convened to agree upon and sign a declaration, setting forth their "loyalty and firm intentions to defend His Majesty's just interests and lawful power, with the person of the Lord Willoughby." Cromwell, however, found the Barbadians too much for him, and he was obliged to make an arrangement very favourable to the islanders, embodied in an agreement dated January 17th, 1652, between certain Commissioners, appointed on behalf of the Commonwealth by Sir George Ayscue, the Admiral in command of the Fleet, and on behalf of the Colony, by Lord Willoughby. Under this agreement, "the Island of Barbados, with all the forts, sconces, and fortifications thereof, and all the artillery, public arms, and ammunition," were to be delivered up into the hands of Sir George Ayscue for "the use of the States of England" by a specified time. No punishment was prescribed to the rebels, and Lord Willoughby was granted liberty "to go to England, and there to stay or depart at his pleasure, without having any oath or engagement put upon him, he acting or attempting nothing prejudicial to the State or Commonwealth of England." It was also provided that an "Act of indemnity be, with all convenient speed, passed in the Parliament of England to save, keep harmless and unquestionable all and every the inhabitants of this Island that are comprised in these Articles for or concerning any act or thing whatsoever done by them, or any of them at any time or place," and, moreover, ordered "that an Act made the 3rd day of October, whereby the inhabitants have been declared traitors, may upon this accord be taken off the file from the records."

This agreement was signed on January 17th, 1752, and the Government of the Colony passed into the hands of Sir George Ayscue, representing the Commonwealth. Notwithstanding the terms of the agreement, on March 4th of the same year a new Legislature which had been summoned, passed an Act by which Lord Willoughby was ordered to embark in a ship for England under penalty of being considered an enemy to the peace, nor was he to return unless permitted by Parliament. On the same day another Act was passed, banishing Colonel Humphrey Walrond, Mr. Edward Walrond, Colonel Shelley, Major Byam, Lieutenant-Colonel Guy, Colonel Ellis, Captain Jarmin, Captain Bowcher and Captain Usher.

Sir George Ayscue left Barbados on March 29th, 1652, having previously signed an Act of the Legislature authorising Colonel Daniel Searle (one of the Commissioners under the agreement) to assume the government without dissolving the Assembly, and another providing that all Acts

Hosted by Google

passed under Lord Willoughby for the defence of the island were to be "repealed, expunged and blotted out of the books of records to the intent that they may be no more seen and perused, but buried in oblivion."

Lord Willoughby returned to Barbados as Governor in August, 1663, after the Restoration, but was lost in a hurricane off the island of Guadeloupe, on or about August 4th, 1666, and was succeeded by his brother, William, Lord Willoughby, who arrived in the island in June, 1667.

G. T. CARTER,
Late Governor, Barbados.

OBITUARY.

SIR (JOHN) IRVING COURTENAY. — The death occurred on October 22nd, at his residence in St. James's Court, of Sir (John) Irving Courtenay. Born in 1837, Sir Irving was educated at Cheltenham and Trinity College, Oxford, and subsequently, in 1861, called to the Bar by Lincoln's Inn. He was a pioneer of the electrical industry in this country, and was interested in a number of undertakings, at home and abroad. He was also a keen politician, being the first chairman of the City of London United Liberal Association. He received the honour of knighthood in 1907. He joined the Royal Society of Arts in 1892, and in addition to this was a member of the Institute of Electrical Engineers and a Fellow of the Royal Geographical Society.

HYLTON WILLIAM DALE.—Mr. Hylton W. Dale died on October 26th at the age of fifty-six. He was educated at University College School, and in 1872 entered his father's business, Messrs. Charrington, Sells, Dale & Co., of which firm he became a partner in 1881. For forty years he was well known on the London Coal Exchange, where he was recognised as an authority on the coal industry. He served for some years on the committee of the Coal Merchants' Society, and was one of the original committee of the Coal Trade Benevolent Association. He became a member of the Royal Society of Arts in 1905.

GENERAL NOTES.

MEMORIAL TABLETS.—A bronze tablet has been affixed by the London County Council to No. 36, Onslow Square, South Kensington, the residence of William Makepeace Thackeray from 1854 to 1861. It was here that he wrote the "Lectures on the Four Georges," the end of "The Newcomes," and "The Virginians," part of "Philip," and many of the "Roundabout Papers." This is the fourth of Thackeray's homes to be commemorated—the others being No. 28, Clerkenwell Road, where he boarded during part of his school time at Charterhouse; No. 16, Young Street, Kensington; and No. 2, Kensington Palace Green, where he died. The tablet on the last-mentioned house was erected by the Royal Society of Arts before this work had been handed over to the London County Council. A tablet has also been placed on No. 9, Arlington Street, which was the residence of Charles James Fox during the parliamentary sessions of the years 1804–1806.

COTTON WORM AND BOLL WORM COMMISSION, EGYPT.—In view of the serious losses which cultivators in Egypt have experienced during recent years through the ravages of the Egyptian cotton worm (*Prodenia litura*) and the boll worm (*Earias insulana*), His Highness the Khedive has approved the formation of a special commission, under the presidency of His Highness Prince Hussein Pasha Kamil, to investigate the means of preventing the recurrence of these pests, or of destroying them when they appear, thereby assuring that the cotton crop shall not remain liable to such disastrous consequences as hitherto. In order that the investigation should be as complete as possible, the Commission, at the first meeting, appointed a sub-committee, including two reporters, selected from among the technical and scientific members of the Commission itself, whose duties, in addition to that of carrying out original experimental work, consist of the examination of all schemes and suggestions presented to the Commission. The Commission invites the co-operation of agriculturists and men of science throughout the world, and has directed the sub-committee to prepare, publish, and circulate accounts of the exact nature of the two pests mentioned above, in such a manner that they may be clearly understood by all. It is contemplated that, with the information thus supplied, a sufficient indication of the local conditions may be conveyed to enable suggestions to be sent in for consideration, which have been prepared by persons not necessarily personally acquainted with Egyptian agriculture. The sub-committee will undertake experiments with any process suggested, which indicates a reasonable probability of success, but cannot employ any chemical mixture the component parts of which have not been made known. No attention can be given to methods involving secret processes or remedies. All communications upon the subject of remedies or with regard to further information upon any point should be addressed to the sub-committee, "Commission du Ver du Coton et du Ver de la Capsule," Department of Agriculture, Egypt.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, NOVEMBER 4...Farmers' Club, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Mr. Hart-Synnot, "The Development Fund and its Distribution."

Engineers, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 7.30 p.m. Mr. W. P. Durtnall, "The Generation and Electrical Transmission of Power for Marine Transportation."

Hosted by Google

Chemical Industry (London Section), Burlington House, W., 8 p.m. 1. Messrs. Clayton Beadle and H. P. Stevens, "The Nitrogenous Constituent of Para Rubber and its Bearing on the Nature of Synthetic Rubber." 2. Mr. A. J. Hale, "The Corrosion of Metals and Alloys in various Solvents." 3. Messrs. A. E. Dunstan and J. F. Strevens, "The Viscosity of Lubricating Oils."

Geographical, Burlington-gardens, W., 8.30 p.m. Miss Ellen Churchill Semple, "The Geography of Japan and its Economic Development."

British Architects, 9, Conduit-street, W., 8 p.m. President's Opening Address.

TUESDAY, NOVEMBER 5...Cold Storage and Ice Association, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 7.30 p.m.

Alpine Club, 23, Savile-row, W., 8.30 p.m. Mr. E. Teichelmann, "Some New Ascents from the West Coast in the New Zealand Mountains."

Civil Engineers, in the Rooms of the Institution of Mechanical Engineers, Storey's-gate, S.W., 8 p.m. Inaugural Address by the President, Mr. R. Elliott-Cooper.

WEDNESDAY, NOVEMBER 6...Sanitary Engineers, Institute of, Caxton Hall, Westminster, S.W., 8 p.m. Mr. W. Marriott, "Meteorology and Public Health."

Geological, Burlington House, W., 8 p.m. 1. Professor Albert Charles Seward, "A Contribution to our Knowledge of Wealden Floras, with special reference to a Collection of Plants from Sussex." 2. Mr. Ernest Proctor, "Notes on the Discovery of Fossiliferous Old Red Sandstone Rocks in a Boring at Southall, near Ealing." With an Appendix on the Upper Devonian Fish-Remains, by Dr. A. Smith Woodward.

Public Analysts, at the Chemical Society's Rooms, Burlington House, W., 8 p.m. 1. Mr. Norman Evers, "The Detection and Estimation of Arachis Oil." 2. Mr. A. C. Chapman, "The Examination of Chinese and Japanese Wood Oil." 3. Mr. H. F. V. Little, "The Estimation of Maganese by the Bismuthate Method." 4. The President will exhibit an apparatus for testing the purity of water by measurement of its electrical conductivity.

United Service Institution, Whitehall, S.W., 3 p.m. Major-General L. B. Friend, "Some Problems of British Coast Defence."

Royal Society of Literature, 20, Hanover-square, W., 5.15 p.m. Professor Henry Newbolt, "Poetry."

Royal Archæological, at the Society of Antiquaries, Burlington House, W., 4.30 p.m.

British Academy, in the Theatre, Burlington-gardens, W., 5 p.m. (Schweich Lectures.) Rev. C. H. W. Johns, "The Laws of Israel and Babylon." (Lecture I.)

THURSDAY, NOVEMBER 7...Cyclists' Touring Club (Metropolitan District Association), at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Rev. M. Le Marinel, "With Cycle and Camera through Five Countries."

Linnean, Burlington House, W., 8 p.m.

Chemical, Burlington House, W., 8.30 p.m. 1. Messrs. W. G. Glendinning and A. W. Stewart, "Some Time-reactions suitable for Lecture Experiments." 2. Mr. J. Kendall, "The Problem of Strong Electrolytes." (Preliminary note.) 3. Messrs. I. M. Heilbron and J. A. R. Henderson, "Action of Semicarbazide Hydrochloride upon the P-quinones." (Preliminary note.) 4. Messrs. A. G. Green and S. Wolff, "Aniline Black and Allied Compounds." (Part III.) 5. Messrs. A. G. Green and F. M. Rowe, (*a*) "Nitro Hydrazo Compounds. Part III.—Influence of Ortho Groups on their Formation and Condensation." (*b*) "The Existence of Quinonoid Salts of Orthonitro Amines and their Conversion into Furazane-oxides." 6. Mr. E. A. Werner, "The Interaction of Azoimide and Nitrous Acid." (Preliminary note.) 7. Messrs. P. C. Ray and R. L. Datta, "Methylbenzyl-, Ethylbenzyl- and Allylammonium Nitrites." 8. Mr. E. de B. Barnett, "Note on the Action of Ethylene Oxide on Hydrazine Hydrate." 9. Mr. J. C. Philip, "Note on the Hydrolysis of Acetic Anhydride." 10. Mr. T. V. Barker, "Studies in Chemical Crystallography. Part I.—Coordination, Isomorphism, and Valency." 11. Messrs. A. Hopwood and C. Weizmann, "Condensation of Bromo-acylhalides with Glucosamine." (Preliminary note.) 12. Messrs. W. H. Mills and W. H. Watson, "Note on the Formation of Tetrachlorophthalyl Chloride by Chlorination of Tetrachlorophthalide." 13. Messrs. J. Ferns and A. Lapworth, "Note on the Preparation and Properties of Sulphonic Esters." 14. Messrs. R. T. Hardman and A. Lapworth, "Electromotive Forces in Alcohol. NOTICES.

ARRANGEMENTS FOR THE SESSION.

The Opening Meeting of the One Hundred and Fifty-Ninth Session will be held on Wednesday evening, November 20th, when an address will be delivered by LORD SANDERSON, G.C.B., K.C.M.G., Vice-President and Chairman of the Council. The chair will be taken at Eight o'clock.

The following arrangements have been made for meetings before Christmas:—

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

NOVEMBER 27.—HAROLD COX, "The Interdependence of Morals and Economics." SIR GEORGE RANKEN ASKWITH, K.C.B., K.C., will preside.

DECEMBER 4.—A. ZIMMERMANN, "The Manufacture of Sugar from Wood, and its Economic Importance."

DECEMBER 11.—DR. F. MOLLWO PERKIN, "Synthetic Rubber."

DECEMBER 18.—JOSEPH PENNELL, "The Pictorial Possibilities of Work." (Illustrated by a collection of etchings, prints, drawings, and paintings from the time of Rembrandt to the present, including a series of lithographs made at the Panama Canal by the author.)

COLONIAL SECTION.

Tuesday afternoon, at 4.30 o'clock:—

NOVEMBER 26.—W. H. WARREN, LL.D., M.Inst.C.E., M.Am.Soc.C.E., Dean of Faculty of Science and Challis Professor of Engineering, University of Sydney, "The Hardwood Timbers of New South Wales." The RIGHT HON. SIR GEORGE HOUSTOUN REID, G.C.M.G., D.C.L., K.C., High Commissioner for Australia, will preside.

INDIAN SECTION.

Thursday afternoon, at 4.30 o'clock:—

DECEMBER 12.—J. FORREST BRUNTON, "The City of Karachi."

Papers to be read after Christmas:—

LEON GASTER, "The Economic and Hygienic Value of Good Illumination."

F. G. OGILVIE, C.B., LLD., "The New Science Museum."

MRS. COOKSON, "The Imitative Jewellery of the 18th Century."

ERNEST E. JESSEL, "The Cambodian Sculptures of Ankhor-Thom."

ERNEST MARRIAGE, "The Adulteration of Jam."

C. L. MACCARTHY, "Steel Pipes versus Cast-Iron Pipes for the Conveyance of Gas, Water and Air."

WALTER C. HANCOCK, B.A., "The Physical Properties of Clay."

ANEURIN WILLIAMS, "Co-partnership."

JAMES BUCKLAND, "Ostrich Farming as a British Industry."

E. RUSSELL BURDON, M.A., "The Development of Research Work in Forest Products."

EDMUND STREET and LIONEL JACKSON, "Advertising."

G. F. KEATINGE, C.I.E., I.C.S., "Agricultural Progress in Western India."

SIR WILLIAM LEE-WARNER, G.C.S.I., M.A., LL.D., "Kathiawar."

SIR JOHN BENTON, K.C.I.E., "Irrigation in India."

C. E. W. BEAN, M.A., B.C.L., "The Colonial Wool Industry."

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

January 16, February 13, March 6, April 17, May 29.

Hosted by Google

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

January 28, February 25, April 29.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., "Methods of Economising Heat." Three Lectures.

December 2, 9, 16.

PROFESSOR VIVIAN B. LEWES, "Liquid Fuel." Three Lectures.

January 20, 27, February 3.

CYRIL DAVENPORT, V.D., F.S.A., "The Art of Miniature Painting." Three Lectures.

February 10, 17, 24.

FRANCIS WILLIAM GOODENOUGH, "Coal Gas as a Fuel for Domestic Purposes." Two Lectures.

March 3, 10.

PROFESSOR JOSEPH ERNEST PETAVEL, M.Sc., F.R.S., "Aeronautics." Three Lectures.

March 31, April 7, 14.

DAVID SOMMERVILLE, B.A., M.D., M.R.C.P., D.P.H., "Antiseptics and Disinfectants." Three Lectures.

April 21, 28, May 5.

JUVENILE LECTURES.

Wednesday evenings, January 1 and 8, 1913, at 5 o'clock:—

CHERRY KEARTON, "Natural History." Illustrated by the cinematograph.

ADDRESS TO THE ROYAL SOCIETY.

At a meeting of the Council of the Society, held on Monday, November 4th, LORD SANDERSON, G.C.B., K.C.M.G., Chairman of the Council, presiding, the following address to the Royal Society on the occasion of the Two Hundred and Fiftieth Anniversary of its foundation was approved and ordered to be sealed:—

The Royal Society for the Encouragement of Arts, Manufactures and Commerce welcomes the opportunity which has been afforded to it of offering its warm congratulations and best wishes to the Royal Society on the Two Hundred and Fiftieth Anniversary of its foundation.

Among the many services which the Royal Society has rendered to this country, and to science in general, one—not the least—has been that, in proportion as the increase of knowledge has rendered necessary special and separate study of each branch of investigation, the Society has been instrumental in the formation of fresh associations for this purpose, while itself maintaining a general interest in the whole field of progress and discovery. The Society of Arts, in whose foundation a century and a half ago several Fellows of the Royal Society took a prominent part, has from its commencement looked to the Royal Society as the parent of such associations in this country, no less than the model for similar combinations abroad, and congratulates itself on the close connection between the two Societies which has been maintained throughout its existence by the presence in its ranks of many distinguished Fellows of the Royal Society. The Council have had pleasure in deputing their Chairman to represent them among the distinguished crowd of delegates who have come from all countries of the world to take part in the celebration of this auspicious anniversary, and they desire to express their earnest hope that the future may have in store for the first and greatest of English scientific societies achievements no less illustrious and beneficial to mankind than those which are recorded in its past history.

Sealed with the Seal of the Royal Society for the Encouragement of Arts, Manufactures and Commerce, in the presence of

SANDERSON, *Chairman of the Council*,
H. T. WOOD, *Secretary to the Society*.

November 4th, 1912.

INDIAN SECTION COMMITTEE.

A meeting of the Committee of the Indian Section was held on Wednesday afternoon, the 6th inst. Present:—

Sir George Birdwood, K.C.I.E., C.S.I., LL.D., M.D. (in the chair), Sir Arundel T. Arundel, K.C.S.I., Sir M. M. Bhownaggree, K.C.I.E., Right Hon. Sir Henry Mortimer Durand, G.C.M.G., K.C.S.I., K.C.I.E., Sir Philip Perceval Hutchins, K.C.S.I., R. A. Leslie Moore, I.C.S. (Retired), Alexander Falconer Wallace, Sir James Wilson, K.C.S.I., Colonel Charles Edward Yate, C.S.I., C.M.G., M.P., with Sir Henry Trueman Wood, M.A. (Secretary of the Society), and S. Digby, C.I.E. (Secretary of the Section).

CANTOR LECTURES.

The Cantor Lectures on "The Loom and Spindle: Past, Present and Future," by Mr. Luther Hooper, have been reprinted from the *Journal*, and the pamphlet (price one shilling) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi.

Hosted by Google

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

OCEAN WAVES, SEA-BEACHES, AND SANDBANKS.

By Vaughan Cornish, D.Sc., F.R.G.S., F.G.S.

Lecture II.—Delivered January 29th, 1912.

On the Principles which Govern the Transportation of Sand and Shingle by Tides and Waves, with a Note on the Severn Bore.

Having embarked upon the study of sea waves in the year 1895, I presently found that, as far as related to deep-sea waves, a theoretical basis of knowledge had been securely laid by mathematicians, but that further observations and measurements were required. Bricks, as the saying is, cannot be made without straw, and the mathematicians had used up all the straw which had been provided for them.

In regard to the action of tides and waves in the transport and accumulation of detritus upon our coasts, I found on the contrary, that a large body of facts of observation were generally accepted (many of which I verified for myself), but that the explanations offered were various and contradictory. Thus it was known that on the south coast of England the shingle drifts, on the whole, up-channel, but this was by some explained on the supposition that the flood-tide current ran more swiftly than that of the ebb, whilst others held that it was due to the circumstance that westerly winds are more frequent, and generally cause larger waves, in the Channel than winds from the east.

Whilst, therefore, my contributions to the knowledge of deep-sea waves have been by way of obtaining fresh facts, which find their explanation in the received theory, my observations on our coasts have led me chiefly to a thinking-out of the proper explanation of facts already known. I have based myself throughout upon the well-established theory of wave-motion in water; but another kind of thinking had to be done at the same time—viz., on the effect of the rate of settlement of particles of different sizes through water, which leads to the separation of shingle and sand from one another.

I now proceed to set out shortly the principles which I consider govern the observed transport of detritus upon our shores.

On the proper action of Waves outside the Breaker Line to drive Sand and Shingle in the direction of their own advance.

The first principle which I desire to establish is that oscillating waves, apart from any motion of translation, have a specific action to drive sand and shingle in the direction of their own advance. When a beach has been piled to a certain steepness the back-slope counteracts this.

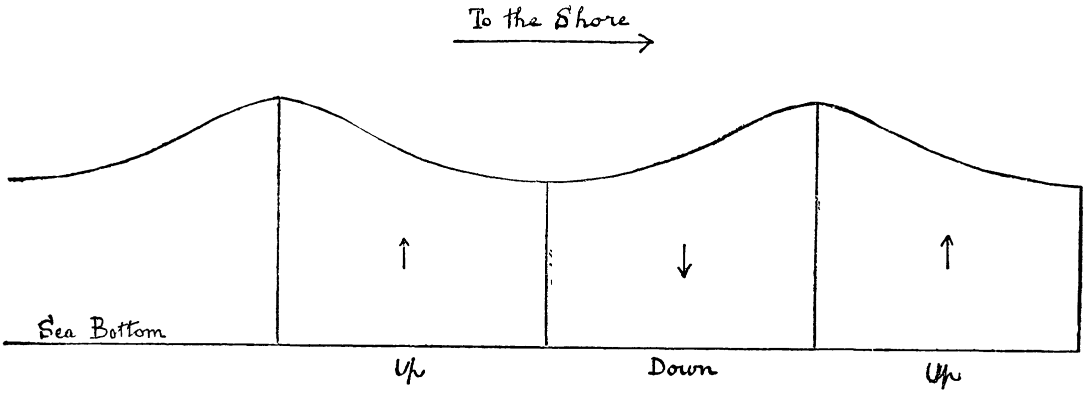
The case I take for explanation is that of waves travelling in water of a uniform depth (*see* Figure). As a matter of established theory, which it is easy to verify approximately by ordinary observation, the water-particles begin to rise as the trough passes. At the first node or shoulder the forward current sets in, the upward current continuing. As the crest passes the water begins to subside, the forward current continuing. As the second descending node or shoulder passes a backward current sets in, the water still subsiding, and it continues to subside until the trough is reached, when the upward movement once more commences, the backward current continuing. Thus the upward and downward movements of the water do not set in at the same time that the forward and backward currents respectively commence, but at intermediate times. Let us see how this peculiar succession of events affects the movement of the sand upon the bottom. Sand settles at a slow rate through water. Conversely, a moderate upward motion of the water is sufficient to suck it up from the bottom and maintain it in suspension. Thus, when the trough passes, and the upward movement of the water begins, sand is thrown into suspension. Consequently, when the forward current commences at the first or ascending node the water is charged with sand in suspension which is swept forward. The upward movement continues until the crest arrives, during which time more sand is continually being thrown into suspension. When the crest passes the water begins to subside, and no more sand is thrown into suspension, but that which is already suspended is still swept on by the forward current which continues until the second shoulder or node is reached; then the backward current commences; but the movement of the water being still downwards, no sand is now being thrown into suspension, and, moreover, some of that previously in suspension has again settled to the bottom. Thus, during the first half of the backward flow the water is being clarified; therefore the quantity of sand swept backwards is correspondingly less. The upward motion commencing as the trough passes, sand

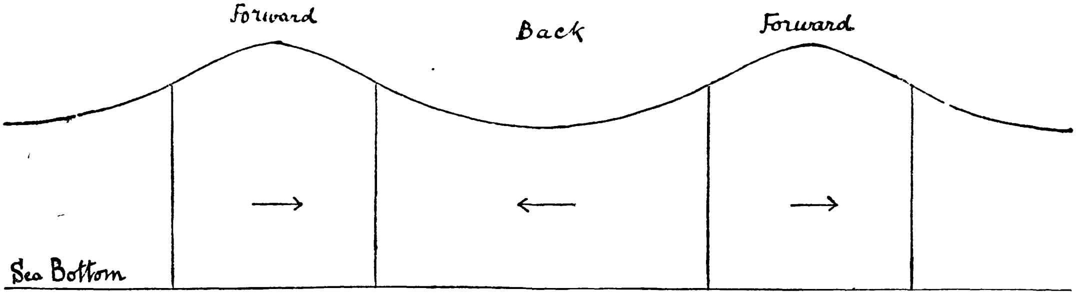
Hosted by Google

is once more churned up from the bottom, so that for the second half of its duration the backward current acts upon an increasing charge of sand, but this backward transport is much more than neutralised by the forward current, which, setting in at the ascending node, acts from the first upon water charged with suspended sand.

Thus the order of succession of the vertical and horizontal movements of wave-water secures a predominant forward movement to the sand when the water is sufficiently shallow for the waves to churn it up from the bottom. The differential effect upon shingle is similar but more marked on account of its more rapid subsidence. The stones are loosened from their anchorage by the upward movement of the water, and swept forward as the crest passes, but, except in very rough weather, they are again firmly anchored when the backward current commences at the descending node.

On the Action of Breakers to form a Beach.—The sand and shingle supplied to the breaker from behind are thrown forward and piled up in a ridge or beach. When the beach attains a certain steepness the reverse slope neutralises this action. The action on which beach-building depends is percolation. When a deluge of water is launched upon a heap of stones the liquid gradually sinks in and fills the cavities. Thus when the breaker flings water upon a beach the water returns by gravity, and the depth of the current which returns down the surface is less than that of the water which flowed up it. Thus by loss of buoyancy and by stranding beaches are built up. The action is more marked in shingle than in sand, first because percolation is quicker, and secondly because larger particles are more readily stranded. An exaggeration of the same effect is seen in the "wrack" or fringe of large and light objects, pieces of wood, shells, and so forth, which marks the furthest reach of the wash of the breakers upon a beach.





On the predominant Drift of Sand and Shingle in the Direction of the Flood Tide.—The influence of the tide upon the transport of the detritus which lies between low and high water-mark can only be understood by considering together the vertical and the horizontal movements of tide-water. The proportion of the horizontal to the vertical components is very different from that in wind-formed waves, but the order of their succession is the same; that, namely, which is the necessary accompaniment of the advance of a superficial wave under the action of

Hosted by Google

gravity. When the tide advances freely, as in mid-channel, the movements are exactly as shown in the figure for wind-formed waves, but they are more easy to remember on account of the circumstance that the vertical and horizontal currents of the tide have familiar names. The upward current is called the Rise, the downward current the Fall, the forward current the Flood, the backward current the Ebb. Much confusion arises, however, from the neglect of students to keep this four-fold aspect of the tides clearly in mind. Where the tide flows freely, as it does approximately midway between shores at the entrance to the English Channel, it begins to flow at the ascending node, *i.e.*, when the level of the water is half-way between low and high, and continues to flow until the descending node is reached, *i.e.*, half-way between high and low water on the falling tide. Thus the flood tide is a current running up-channel from the time of mean sea-level of the rising water past the time of high water until the time of mean sea-level of the falling water.

Conversely, the ebb tide is a current running down-channel from the time of mean sea-level of the falling water past the time of low water until the time of mean sea-level of the rising water.

Past headlands and salient positions on the coast, the flood and ebb set in at nearly the same times relatively to the commencement of the rise and fall.

Therefore, in such situations most of the area between high and low water-mark is covered by the sea during most of the time of flood tide, *i.e.*, when the water is running up-channel, and all of it is covered during part of this time. Conversely, most of the area between high and low water is beyond the reach of the sea during most of the time of ebbing tide, and all of it during a part of that time. As, moreover, most of the beach material lies above mean sea-level, and the beach is thickest at the top, it follows that on promontories and salient positions the transport of detritus lying between high and low water is mainly achieved whilst the tide is flowing, *i.e.*, while the current is running up-channel.

The velocity of the tidal currents in fairly deep water off the coasts of Great Britain is known. Their velocity in the shallow water between low and high water-mark has not been made the subject of such detailed observations. That it is generally less than that a little further out is probable. That it is, however, often considerable is known from ordinary experience, When there is a rough sea upon a sandy shore, the water for some distance behind the breakers is turbid from particles of sand in permanent suspension, and these particles must drift a long way, sometimes probably miles, in the course of a single tide. It is evident, therefore, that whereas it is the waves which churn up the sand and place it in suspension, the tidal current must largely affect its longshore transportation. This is in accordance with the general opinion derived from observation. It follows, further, from what has been said above, that in salient positions the tidal drift of the sand between high and low water must be predominantly in the direction of the flood tide, because during ebb tide the material is to a great extent beyond the reach of the sea. For this reason the action of the flood tide upon sand will predominate, even if the velocity and duration of the flood and ebb be equal.

In bays and inlets the obstructing shore, accelerating the accumulation of an opposing head of water, makes high water earlier than it would otherwise be. The momentum of the flood current is by this opposition sooner exhausted, so that the ebb begins sooner after high water than it does off headlands. Thus in bays and inlets the difference between the flood and ebb in their power to transport sand is less than on headlands and salient positions. As the actual tidal transportation is simply the difference between the effects of flood and ebb, it follows that, apart from all other influences, there will be a tidal accumulation of sand in bays and inlets at the expense of headlands and salient positions.

There are also exceptional positions called tidal nodes where the tide begins to ebb almost at the same time as it begins to fall. A notable case is the line from a little west of Dungeness to the French coast, where the tide which comes up the English Channel opposes that from the North Sea. In such positions the resultant tidal transportation will be a minimum, unless any peculiar circumstance intervene, because the average water-level during ebb is nearly the same as during flood.

I am not able at present to lay down useful general principles for positions such as I suppose must exist where the ordinary backward and forward swing of flood and ebb is replaced by a horizontal circulation of water about a vertical axis. I have, however, dealt with a particular case, which is somewhat of this kind.*

* See "Waves of the Sea and other Water Waves," pp. 206–211: "On the Production and Maintenance of the Shambles Sandbank near Portland."

It remains for me to deal with the question —to what extent the tidal currents affect the littoral drift of shingle. It is not in dispute that the direction of this drift on the shores of England is generally in the direction of the flood tide, but it happens that in most exposed places on our coasts the flood tide comes from the same direction as the heaviest waves or the prevailing winds, or both. It is also not in dispute that the tidal currents on our coasts do not disturb the shingle when there are no waves. It is the waves which loosen the shingle from its anchorage on the bottom and keep it moving. The stones are generally only partially buoyed up by the churning action of the waves, and are at most only momentarily suspended.

The debated question is whether the longshore tidal current sweeps along the stones when in this loosened and lightened condition. Observations have been attempted, and opinions have been formed from them, but no one has yet produced observational evidence convincing to all persons who have given attention to the subject. I proceed to set forth the theoretical reasons which I consider show that in exposed positions, headlands and the like, the tidal currents do sweep the shingle along whenever waves beat upon the shore. Suppose the wind to be dead on-shore, and that there is no "swell," then the only breakers are those whose fronts are truly parallel with the shore.

First, take the time of slack tide. Suppose the breakers to beat upon bare shingle and the water falling thus from a height, but in an inclined direction, to have a horizontal velocity of five miles per hour. The shingle will be moved up and down the beach, but there will be no longshore drift, for the current will be at right angles to the shore. Next, let us suppose that there is throughout the narrow strip of water above low water mark a uniform longshore tidal current of one mile per hour. The differential movement of the sea-water which causes the breakers is still at right angles to the shore. But each particle of water which falls under the action of gravity from the breakers' crest starts with a lateral or longshore movement of one mile per hour. Its blow upon the shingle is, therefore, not delivered at right angles to the shore, but at an angle thereto, and thus the longshore drift of the shingle is produced. If the speed of the tidal current be greater the amount of this drift will be increased even though the waves remain as before. If waves come obliquely in the same general direction as the tidal current, the drift due to the differential, or wave, motion is increased by the current. If the current be against the waves the drift caused by them is correspondingly diminished. If throughout the year the oblique waves come equally from either hand, the whole resultant shingle drift will depend solely upon the amount of longshore tidal motion of the wave-water. I have pointed out that during the flowing tide more of the area between tide marks is covered by water than during the ebbing tide, and that this gives the flood tide a preponderance over the ebb in the transport of the *sand* which lies between tide-marks. But the shingle lies for the most part above mean sea-level, although there are local exceptions. Thus shingle drift in exposed positions goes on almost wholly during the hours of the flood tide. It follows, therefore, that with waves equally from both quarters the drift of the shingle will be in the direction of the flood tide. It equally follows that the observed drift in situations chiefly exposed to winds and waves from the same direction as the flood tide is partly due to that prevalence of wind and wave and partly to the current of the flood tide itself.

These conclusions differ from those of the Commissioners on Coast Erosion,* who are of opinion that the tidal currents increase the rate of longshore travel of shingle disturbed by waves, but do not, on the whole, determine or materially influence its direction, which they say "is governed" by that of the winds acting by means of the waves which they produce.

On the theoretical grounds already stated I consider the Commissioners to be mistaken. It may be objected that the Commissioners were influenced by the evidence of *observers.* I also have observed, and have found the observations extremely difficult. Once, however, I made an observation of some illustrative value which was clear and easy. It was on the banks of the River Spey—always rapid, and then swollen by melting snows. Small progressive waves came in upon a shelving bank of coarse sand, which under their small currents behaved as shingle, *i.e.*, moved about, but was not thrown into more than momentary suspension. One or two ridges of this coarse sand were formed parallel to the shore, and the on-and-off shore motion of the coarse sand grains could be seen as the wave currents swung to and fro. But all the time I could see how the current was causing a continuous drift of the sand grains parallel to the shore. The applicability of the observation

* Final Report, § 43 (2), pp. 12, 13.

Hosted by Google

depends upon the fact already mentioned that the particles were not in suspension.

Waves are very deceptive to the eye. When standing on a tidal shore they monopolise the attention by their stately movement, by their resounding noise, and by the insistence of their rhythmic repetition; and all the while the tidal current flows by, silent, invisible, unnoticed, but steady, continuous, and persistent.

ON THE SEVERN BORE.

In a river the duration of the flood tide is less than that of the ebb. The backing-up of the land-water produces a "head" which reverses the current before its time, so to speak, and the contraction of the channel contributes to this effect. Conversely, the momentum of the land-water flowing down hill towards the sea enables the ebbing waters to continue flowing, so to speak, beyond their time.

The rise of tide in the Bristol Channel is very great, and causes the tide in the River Severn to extend beyond the summit of those miles of steep gradient which extend from the Shepherdine Sands to Hock Cliff. Between these places the permanent banks of the Severn have the funnel shape which is characteristic of a tidal estuary, and at high water the river has the estuarine appearance. Between the permanent banks, however, are great stretches of loose sand, and during most of the hours of ebbing tide the river follows a course through winding channels which it has incised in the sandbanks, this sinuous course having the characteristic form of a river channel in an alluvial plain.

In the lower part of the steep gradient, viz., between Shepherdine Sands and Severn Bridge, can be seen in the sands at low water dry channels, or swatchways, along chords of the semicircular arcs of the winding course of the ebbing stream. When the incoming waters of the flood tide here encounter the ebbing stream, they are by it pressed aside into these by-channels, which are filled by the incoming flood-water before the current in the ebb channel is reversed. Presently the water in the by-channel or swatchway, rising above the level of the intervening sandbank, sweeps across it in a broad sheet, and enters the ebb channel sideways. A short period of somewhat turbulent eddying ensues, after which the current is found to be up-stream, *i.e.*, the tide is flowing all across the river at the position in question. Higher up, however, much the same process is repeated at each bend of the winding ebb channel until Severn Bridge is reached. Above this place, there being a greater proportion of land-water and a smaller proportion of sea-water, the ebb channels are more deeply incised, and their banks being high, the waters of the incoming flood tide are confined between them until a sufficient head has accumulated to overcome the momentum of the ebbing water, and the front of the flood tide makes its way directly up the ebb channel. It does so usually in the form of a bore, a steep-fronted breaking wave 1 ft., 2 ft., or 3 ft. high, occasionally, perhaps, higher. Immediately after the bore has passed any spot the current, which until then was ebbing seawards, is found to be flowing swiftly up-stream. Such is the effect of the distribution of the sandbanks in determining whether a bore shall or shall not arise in an estuary where the steepness of the gradient, the shallowness of the water, and the greatness of the tidal rise, are favourable to its formation.

In dry seasons the waters of the flood tide rearrange the sandbanks so as to facilitate the rise, the tide making cut-off channels across the chords of the arc-like ebb channels, and avoiding the conflict of a wave by means of an easy circulation. Thus, after a dry summer, there are only small bores formed even in the great tides of the early autumn.

After a period of heavy rains, on the contrary, the sinuous ebb channels are so deeply incised that the flood tide has no alternative but to battle with the ebb, and when the high equinoctial tides follow a rainy season, great bores are formed.

I have referred in the preceding sections of the paper to the relation of my own wave observations of the last seventeen years to the established theory of water-waves. In the matter of deep-sea waves I have added new observations required to advance the subject on the lines of the theory. In the matter of littoral drift I have applied the same theory to the explanation of facts observed before my time and re-observed by myself.

Only in the matter of tidal bores, as illustrated by the Severn Bore, do I find that my observations show the necessity for a modification of the hitherto accepted theoretical treatment of waves. The tidal bore has always been treated as the steepened front of the whole tidal wave. In other words, it was said that the tide advanced up a river with a bore when the retardation was such as to make the first rise of the tide sufficiently sudden to form a high, steep face. Sir G. H. Darwin, however, had pointed out that the theory served rather to explain a rapid rise than an absolutely sudden one.

Hosted by Google

Now, if the theory had been correct, the length of the wave of which the bore was supposed to be the face or front slope would be many miles. Consequently, in the case of the Severn, for instance, the wave-length would be indefinitely great as compared with the depth at low water. Consequently the only change of appearance of the bore in passing from the shallows to the pools of the river between Newnham and Gloucester would be that in the pools the speed would be greater and the height less.

I have observed, however, on more than one occasion, and in more than one place, that this is not at all what happens. The bore advances across a rocky shoal, such as Denny Rock, with a steep, breaking front, and, at all events when seen from a low standpoint in front, appears to be a solitary wave; but, when it passes into the pool beyond, the steep front disappears, and the breaking, solitary, or almost solitary, wave is replaced by a rounded billow which multiplies itself to leeward, a group of as many as sixteen such waves being rapidly formed. Thus it appears that the disturbance which constitutes a bore in the Severn has a wave-length long, perhaps, as compared to the depth of water at low tide in the shallows, but certainly short as compared to the depth of water in the pools.

Observation shows that the rise of a tide is never perfectly steady, but is pulsative in time and, therefore, undulatory in space. I think that a bore in the Severn is the steepened front of any one such local swelling of the tide caused by local resistances. I have described elsewhere* how at Hock Cliff more than one bore can be seen running at the same time in different channels, and even in different directions, up-stream, down-stream, and laterally.

* "Waves of the Sea and other Water Waves," p. 246.

THE MANUFACTURE OF GLASS CHRISTMAS-TREE ORNAMENTS IN GERMANY.

The acknowledged German centre of the glass Christmas-tree ornament industry is in the Thuringian Mountains, twenty-five miles distant from Coburg, where almost the entire population is dependent upon this industry. It is here that Christmas is really appreciated, and man, wife, and children work uninterruptedly, even the smallest children helping as soon as they can use their hands. In the small village of Lauscha, at the end of the branch railway line running from Coburg, the largest quantities of the glittering Christmas-tree ornaments are made. The processes of manufacture, which are not only instructive and interesting, but also unique, according to the American Vice-Consul at Coburg, are as follows. Fine glass-blowing is done in every house and hut, and the majority of the inhabitants who work on these articles show great talent and dexterity in producing the delicate fragile balls, stars, etc. The glass tubes are bought by the inhabitants from a local glass factory, being either of thick or thin glass, according to the kind of article to be produced. To blow the various ornaments, these tubes are held over the flame of a gas blow-pipe, with a bellows worked by the foot. The tubes are in this manner heated to a point where they become soft, and a light "puff of breath" is then sufficient to expand the glass mass, although the blower must calculate the pressure of air to be blown into the tube with care and dexterity, as otherwise the glass immediately assumes a much larger size than that desired. The professional blowers understand how to give the mass of glass every possible form simply by blowing and pulling. They make animals of every description, a speciality of theirs being reindeer, with their delicate legs and huge antlers. Then there are airships and balloons, while the commoner glass Christmas-tree ornaments, known to every child, are made in profusion. Perhaps the most difficult article made is the imitation carnation or rose, where every individual petal has to be formed separately and then attached to the body. This is done by heat, the various parts being fused on, as is also the case when the bodies of animals have their legs, ears, and all other protruding parts attached. Although the glass article is then finished, it has a very lifeless, disappointing look, and cannot be sold till the necessary "charm and grace" are given by means of colour. All the beauty of the light glass article is brought out by the shining, sparkling colour. The glass-blower, however, does not attend to this branch of manufacture, because highly-coloured glass is very seldom used, for the simple reason that it is too expensive. The colouring of the glass ornaments is generally attended to by women and children. When a finer article is desired it is given to more artistic workers, who understand how to use a brush. Glass balls are painted with rings or other designs, and the other articles are also decorated with a brush. The common round glass balls which are used to decorate the Christmas tree, either singly or strung together in chains, are usually coloured on the inside. This is done either by dipping the article in a thin, cheap, colouring liquid, or gold and silver bronze in a liquid state is poured into the interior. In this manner gold and silver balls are obtained which look pretty and keep their colour a long time, but which, on the other hand, break at the least pressure. Colouring by simply dipping the glass article in a liquid colour is a very easy, mechanical work, which is mostly done by small children. A great deal of care must be taken in packing glass ornaments, as otherwise, on arrival

Hosted by Google

at their destination, the cases would be found full of nothing but thin, sharp pieces of broken glass. Cardboard boxes, divided into twelve compartments, are used, and the glass ornaments, which are sold per dozen, are laid in very light, cheap, cotton batting, which lightens the pressure and prevents rattling, thus protecting the contents. The goods must, of course, be offered as cheaply as possible to ensure large sales, for otherwise the profit to the middleman and merchant would be too small after payment of freight and duty. Consequently the profit of the producer is small; but, as his tastes are simple, the small amount earned looks quite respectable in his eyes. These Christmas-tree ornaments weigh so very little that they are, as a rule, sent to their destination by parcels post instead of being shipped by rail. From the middle of November each year up to Christmas Eve, the number of packages of Christmas-tree ornaments passing through Coburg from Lauscha and the other mountain towns, is so large that not only extra men are needed at the post offices, but also additional carriages have to be attached to every train.

TRANSIT OF SHIPPING VIA THE SUEZ CANAL.

During the first six months of the present year the total number of vessels that passed through the Suez Canal was 3,314, of these 2,825 were steamers and 489 sailing ships, with a total aggregate tonnage of 10,511,618. The total receipts for the transit of these vessels was 70,204,000 francs (£2,808,160) as compared with 68,058,000 francs (£2,722,320) during the corresponding period of 1911, an increase of 2,146,000 francs (£85,840) in favour of this year, notwithstanding the reduction of the dues since January 1st and the coal strike in England of last spring. The following shows the number, tonnage, and percentage of the vessels of the six principal nations in order of importance—

Nationality.	No. of vessels.	Tonnage.	Percentage of total tonnage.
British	1,769	6,668,445	63·43
German	351	1,517,951	14·44
Dutch	171	619,106	5·88
Austro-Hungarian	156	506,852	4·81
French	110	396,887	3·77
Italian	77	195,620	1·85

The remainder, belonging to ten different countries, follow in order of importance—Russia, Japan, Sweden, Denmark, Norway, Spain, Greece, Siam, United States, and China.

The total number of passengers, including troops, carried by these vessels has fallen from 148,955 during the first half of 1911 to 115,177 for the same period during the present year.

The following were the numbers and nationalities of the troops that passed through the canal during these periods each year—

	1911.	1912.
Italian	574	3,514
Turkish	37,899	33
British	12,243	1,338
German	5,475	5,366
French	5,652	5,361
Dutch	890	735

THE SHIPPING AND FISHING INDUSTRIES OF BERGEN.

A report of the Italian Consul at Bergen (Norway) gives some interesting information respecting the shipping and fishing trade at that town. At December 31st, 1911, the merchant fleet of Bergen consisted of 216 cargo steamers, registering a total of 380,000 tons; five sailing vessels, 7,200 tons; and 86 passenger steamers, 40,700 tons; in all, 307 ships with an aggregate tonnage of 427,900. There were, at the same date, six cargo and one passenger steamer in construction. In addition, there were 39 steam launches and motor-boats belonging to the port.

This fleet is owned by seventeen navigation companies and forty-seven private firms, and represents a capital of 84 million kroners * (£4,725,000). The crews number upwards of 6,000 hands.

A company was formed, last year, at Bergen for carrying on whale fishery on the North American coast. It now possesses a steamer of 2,197 tons and four fishing boats to the value of 800,000 kroners (£45,000).

The fishing industry is a very important branch of trade at this port. Last year the sale of dry and salt cod, as well as of cod-liver oil, was less remunerative than usual on account of the high price paid for the fish at the opening of the season; and the abundance of it at the close. The fish-canning industry gave better results last year than previously.

On the whole, the fishing season generally, last year, of Norway may be considered to have been a more profitable one than that of 1910, but the statistics for 1911 are not yet available. The value of the products of the cod fishery, which besides dried and salt fish includes cod-liver oil and cods' roe, amounted last year to 19,200,000

* Norwegian kroner = 1*s.* 1½*d.*

Hosted by Google

kroner (£1,080,000). The herring and other fisheries on the coasts of Norway and Iceland produced 47,300,000 kroner (£2,606,625).

The fishing industry gave employment to 89,926 persons and 18,940 boats in 1910.

With regard to the trade between Italy and Bergen, the exports from this port in 1911 consisted chiefly of 7,444 metric tons (7,326 English tons) dried cod (stock fish); 466 metric tons (458 English tons) salted cod; 1,862 barrels cod-liver oil, and 2,700 kilogs (53 cwt.) preserved fish.

The exports from Italy to Bergen during the same period were chiefly salt and wine. Of a total of 46,458 metric tons of salt imported to this port, Italy figures for 19,557 metric tons (19,249 English tons).

With regard to wine, only 9,000 litres (1,980 English gallons) of Italian growth were imported, as compared with 125,000 litres (27,500 gallons) from Spain, 359,000 litres (78,980 gallons) from Madeira, 152,000 litres (33,440 gallons) from Greece, and 33,000 litres (8,560 gallons) from France.

EMPIRE NOTES.

Canadian Canals.—Water transport is every year increasing in volume in the Dominion, and the systematic development of canals, linking up in a chain the great lakes, is proving an important factor in the distribution of produce and merchandise. The Canadian Railways and Canals Department returns show that the traffic passing through the canals has increased from 17½ million tons in 1908 to 38 million tons in 1911, *i.e.*, it has more than doubled in three years. By far the greater proportion of this tonnage, however, originates in the United States, and millions of tons of iron ore find their way annually through the canal at Saulte St. Marie, from Lake Superior, for the United States black furnaces.

Panama Canal.—Western Canadians are busily preparing for the opening of the Panama Canal, and a company has been formed, under the title of the British Canadian Transport Company, for the purposes of running a regular service of steamers from New Westminster, B.C., to British ports. The congestion of freight, both upon the railways and the existing steamship lines, is a serious matter, and the opening of this new trade route is being eagerly anticipated by the whole western community.

Pulpwood.—The quantity of pulpwood manufactured in Canada in 1911 showed an increase of 73,801 cords (or 12·3 per cent.) over that of 1910. The rise in market values of this product has brought the industry a much greater return in money than the increase in output denotes. The value of the wood returns for 1910 was $3,585,154, and in 1911, $4,338,024, or a net increase of $752,870. The average price of $6·45 per cord secured by the vendors in 1911 is nearly a record, and has not been equalled for years. Considerable attention is being drawn to the vast supplies of available timber in Quebec, and some important developments may be looked for in this Province in the near future.

Australia's New Capital.—The Commonwealth is starting operations on the city water scheme, and it is estimated by the engineers that a sum of £90,000 will have to be expended on the construction of the Cotter River dam. It is not anticipated that more than £9,000 for this purpose will be spent during the present financial year. Tenders are to be called for at an early date, for the laying of a cast-iron main from the site of the dam to the service reservoir, a distance of ten miles. This will probably entail a further outlay of £50,000 to £60,000.

Visit of British Association to Australia.—Australians are preparing for the reception of the 200 to 300 members of the British Association who will visit them from all parts of the Empire in 1914, and the Federal Government has already subscribed £15,000 towards the expenses. The programme of this visit is in the hands of the various scientific bodies throughout Australia. This will be the fifth meeting of the Association held outside the United Kingdom, as the Association has visited Canada on three occasions and South Africa once. The meetings in the various overseas Dominions have been productive of splendid results, not only from a scientific, but from an Imperial point of view, and the congress to be held in Australia is not likely to be an exception. The visitors will find much to interest them, and their tour is sure to prove of value as a stimulant to the useful scientific research that is at present being carried on by different societies throughout that continent. The meetings will be held in Sydney and Melbourne, and special arrangements are being made for an inspection of the Great Barrier Reef, and a steamer will be placed at the disposal of the delegates for this purpose. The party will also visit the north coast and study some of the problems of the northern territory.

Growth of Manufactories in New South Wales.—The Secretary of the Sydney Chamber of Commerce, Mr. J. Maitland Paxton, has recently been visiting London, and in the course of an interview gave some interesting and instructive details concerning the progress of New South Wales' industries. After touching on the principal industries, such as the production of wool, wheat, dairy produce, etc., he dealt with manufactures. According to Mr. Paxton, the value of land and buildings used solely for industrial purposes, at the close of 1909, throughout the Commonwealth was £27,677,595, of which £11,014,362 was the share of New South

Hosted by Google

Wales and £8,642,344 that of Victoria. Mr. Paxton expressed the opinion that the cost of labour in the Commonwealth would preclude, to a large extent, Australian manufacturers from the export market, and considers that they will have to look to the home market for support. The flour mills, according to the same authority, are well equipped and have an output value of £6,000,000 per annum. Another very prosperous industry is the manufacture of agricultural machinery, and this machinery is finding a ready sale in the Argentine, as well as at home. Mr. Paxton echoes the cry for labour, and points out that this need is handicapping the output of many manufactories.

Irrigation in Australia.—Western Australia is following the example set by Victoria and New South Wales, and is seriously turning its attention to the conservation of water during the wet months for distribution during the dry. A bill has just been prepared, and will shortly be submitted to the State Parliament, conferring upon the Minister for Water Supply power to acquire land for irrigation purposes, and to grade, subdivide, and lease it for closer settlement. Already Parliamentary powers have been obtained for the construction of a reservoir near Harvey, one of the finest orange-growing areas in Australia. This reservoir will hold 350 million gallons of water, and will cover an area of 77 acres. This will be the first of several similar projects to be carried out in Western Australia. The Minister of Works, before a large number of visitors, performed the ceremony of opening the sluices at Yancs, and letting the water for irrigation purposes on to the Burrinjuck land. This water has been brought from the Murrumbidgee, a distance of 220 miles. The reservoir in the mountains, where the supply of water is stored, has a capacity of 33 billion cubic feet of water, a volume greater than that of Sydney Harbour itself. The catchment area supplying this water extends over 5,000 square miles. Arrangements are already completed for irrigating 358,000 acres on the north side, and, later on, a large acreage to the south will be served. The authorities estimate that this scheme will ultimately enable 100,000 new settlers to secure profitable holdings, and nearly all the farms in the first sub-division have already been applied for. The capacity of the district for fruit-growing has been tested by the State Government, and for some time past an experimental farm has been operating in the centre of the district. Settlers will be able to secure useful data from the investigations and experiments carried out at the institution.

New Zealand Fisheries.—Those interested in the New Zealand fisheries will watch with interest an experiment which is to be carried out there. The Portobello (N.Z.) Maine Fish Hatchery Board has decided to send their curator, Mr. Anderton, to England, to bring out a shipment of herring ova. Mr. Anderton will visit a number of hatcheries in Great Britain, and will also proceed to Norway, Heligoland, and establishments on the Dutch, Belgian, and northern French coasts. A large stock of lobsters and crabs will be taken out as well, and an attempt will be made to introduce such fish as turbot, haddock, and cod.

New Zealand Butter.—The reports on the quality of New Zealand butter are very satisfactory. For some time California has imported it, and the merchants state that the quality of the butter is so good that it sells evenly with the best Californian production. But this New Zealand product is also making its way in Western Canada, where it bids fair to hold the same position as it does in California. The retail price in Western Canada is 1*s.* 8*d.* per lb.

Ostriches in the Transvaal.—Ostrich farming in the Olifants district of the Transvaal is showing up satisfactorily. Chicks purchased two and a half years ago have developed so well, that the feathers are fetching as much as £20 per pound weight. Quite recently a supply of these feathers was sent to Pretoria for the purpose of exhibition, and expert opinion was to the effect that the Olifants district is producing feathers equal in quality to the very best in South Africa.

Malay States Trade Progress.—A recent report on trade progress in the Malay States shows a steady increase in trade and customs receipts. The population has increased, and the extension of rubber plantations has been a help in this direction. The high price of tin also has contributed to the growth of prosperity, tin being one of the staple products of the peninsula. There has been a considerable increase in the imports of articles of luxury, such as tobacco, cigars, etc., as well as in articles of necessity.

NOTES ON BOOKS.

When Kings Rode to Delhi. By Gabrielle Festing. Edinburgh and London: William Blackwood & Sons. 7*s.* 6*d.* net.

The accomplished authoress of "On the Distaff Side," and "John Hookham Frere and his Friends," needs no introduction from me to the readers of the *Journal* of the Royal Society of Arts of her "When Kings Rode to Delhi"; and, besides, it was but a few weeks ago that, in a paper on "The Rajputs in the History of Hindustan," the *Journal* gave what was in effect a review of Miss Festing's "From the Land of Princes," to which her present volume is a most acceptable and most commendable supplement. The two volumes cover the same period and the same leading current of events; but, whereas the former deals with the Rajput protagonists in that bleeding controversy of over eight centuries, the latter treats of the chief Islamite [Turkman, Afghan, and Mo(n)gol] actors

Hosted by Google

in it; and, again, only in its more heroical, and romantic, and tragical aspects.

There is no continuous Indian history before the Arab conquest of Sindh, A.D. 664–750; and the first assured date in it is that of Alexander's invasion, 327 B.C., "in the month of April," when he defeated "Porus" on the very ground whereon, 2,286 years afterwards, Lord Gough, and Sir Joseph Thackwell, and Sir Walter Raleigh Gilbert gained the decisive battle of Gujerat over the formidable theocracy of the Sikh Khālsā. Although in "From the Land of Princes" the selected legends and traditions of the Rajputs are arranged in the chronological order of the times to which they relate, they were not, and indeed the older of them could not be, systematically dated, and it adds to the value of "When Kings Rode to Delhi," as an introduction to Indian history, or rather the history of Hindustán—after the manner of Scott's "Tales of a Grandfather" to that of Scotland—that each of its successive chapters is headed with the inclusive dates of the incidents it records. But a still firmer grasp of the chronology of the often highly confusing circumstances of the centuries of Islamitic supremacy in Hindustan would have been secured by prefixing to Miss Gabrielle Festing's chapters a synoptical table, on one page, of the leading dates of the whole millennium over which they extend; and I venture to suggest this being done whenever a second edition of this most instructive and inviting volume is in preparation. We may assume about a millennium prior to Alexander's apparition at Attock, during which the aggressive Aryas and non-Aryas of India were more or less closely consolidated into the theocratical race of Brahmanical Hindus, as distinguished from the outcasts of the autochthons of the country, who, during the later centuries of this millennium, became the chief support of the Buddhist [economico-commercial] reaction against the Brahmans. The second millennium runs from Alexander to the invasion of Sindh by the Arabs; and the third [the first that is truly historical], on to the consolidation of the revindication of Aryan supremacy in India, as a consequence of the Sepoy Mutiny of 1857. The tabular statement of this last millennium may be sufficiently given as follows:—

THE ARABS IN SINDH. A.D. 664–750.

THE GHAZNIVIDS [Sabaktegin, "Mahmud of Ghazni," etc.] IN INDÍA. A.D. 978–1118.

THE GHORIANS. A.D. 1153–1206.

THE SLAVE KINGS OF DELHI [invasion of Mo(n)gols, 1217]. A.D. 1206–1288.

THE HOUSE OF KHILJI [Tartars]. A.D. 1288–1321.

THE HOUSE OF TUGHLAK [Tamerlane at Delhi, 1398]. A.D. 1321–1412.

THE SEIADS. A.D. 1412–1450.

THE HOUSE OF LODI [Vasco da Gama at Calicut, 1498]. A.D. 1450–1526.

THE MO(N)GOL EMPERORS [Sir Thomas Roe at Delhi, 1615–1618; Resurrection of the Mahrattas, 1707–1712; Invasion of Nadir Shah, 1738–9, of the Abdalli 1756; Plassey, 1757], A.D. 1526–1857.

That table is readily learned by heart; and it is a clue to the whole of the political history of India; the history of the Deccan being a mere fringe to the history of Hindustan; one might almost say of the pre-"eminent" city of Delhi.

It is needless for me to say anything more in praise of Miss Festing's volume, than that I have read it through, simply because having begun with it, I could not stop reading on and on, until I had ended with it. Only on one point do I seriously disagree with her, and that is in her unreserved condemnation of Humayun, the second Mo(n)gol Emperor of Delhi. He was not a great emperor like Baber, and Akbar, and Jehanghir, Shah Jehan, and Aurungib, but he was a brave and most chivalrous soldier, and one of the most loveable of men; and the idol of his father; who when, at one time, Humayun lay sick unto death, coming to the bedside of his son, passionately and vehemently supplicated, and implored the Almighty to take his life in sacrifice for Humayun's. After a while he cried out—"My prayer has been heard. I have borne it away," and from that moment the youth recovered, and Baber sickened and died, on December 26th, 1530. Miss Festing must help to give this true story of paternal affection and piety—and one of the most remarkable of the efficacy of prayer—a wider perusal in the next edition in this her most fascinating record of the lives and deaths of Turkman, Tartar, and Mo(n)gol kings, who from century to century rode right royally, in all the barbaric pageantry of High Asia, backward and forward between Khorasan, and Ghazni, and Cabul, and Kanouj, and Delhi.

I must quote some of the paragraphs from Miss Festing's "Epilogue" at length. Referring to the depravations of the Mahrattas and Rohillas she writes:—"Hindustan was gradually becoming depopulated at the close of the 18th century, and communication between the few villages that still existed was frequently cut off by the wild beasts that infested the highways. *Save in Rajputana, scarcely any reigning family in India could boast more than twenty-five years of independent and definite political existence.* All over the land Hindu and Muslim looked with longing to the one power strong enough to quench all these disorders and give peace in their time. 'The goodness of the English is beyond all bounds,' wrote a Muslim chronicler, about the year 1764, 'and it is on account of their own and their servants' honesty that they are so fortunate and wealthy.' 'They are a wonderful nation, endowed with equity and justice,' writes another a few years later. 'May they always be happy, and continue to administer justice.' 'When will you take this country?' a fakir asked Mountstuart Elphinstone in 1801. 'The country wants you. The Hindus [he meant the marauding Mahrattas] are villains. When will you take the country?' It was a question asked over and over again; but even after the battle of Buxar [1764] had settled the fate of Bengal, and the storming of Seringapatam [1799] had made it possible to effect the pacification of

Hosted by Google

Southern India, and the Treaty of Basain had decided that the Maratha Confederacy was no longer to spoil and ravage a distracted country, no new ruler was yet proclaimed in Delhi . . . It was in September, 1857, that the Sappers and Miners opened the Kashmir Gate, and the last of the sons of Timur ceased to reign, even in name. It was in December, 1911, that the English King showed himself to the crowds who thronged the city, upon the wall where the Moghul Emperors were wont to stand, and once more made Delhi [the 'Eminent'] the chief city in India, as in the days of old."

Nothing can be more true, more just, more illuminating, than these few simple words, "ab imo pectore"; and nothing more moving and devoutly stimulating.

The printers, and binders, and the publishers have all done their best with the general get-up of the volume; which is illustrated with several colour prints reproduced from Oriental originals; and is bound in green [I hope intentionally], the colour of Islam; even as the volume of "From the Land of Princes" was appropriately bound in Rajput blue. It is only a pity, in this connection, that the two volumes should be of different sizes. It is always distressing to see on one's bookshelves books by the same author of different sizes; and the mistake of it often checks a purchase.

George Birdwood.

A Home-Help in Canada. By Ella C. Sykes. London: Smith, Elder & Co. 6s. net.

At a time when the tide of emigration is flowing so strongly in the direction of Canada, and when the question of sending out women to settle in our colonies is so much to the fore, the appearance of Miss Sykes's volume is very opportune. A patriotic believer in the greatness of the British Empire, Miss Sykes determined to go out and see for herself what are the openings for educated women in the Dominion, and with a view to making her test as practical as possible, she spent six months in various positions as "temporary home-help." The present volume contains an account of her experiences, which were mostly obtained in Western Canada. Upon the whole, and in spite of a glowing enthusiasm for the task of empire-building, it cannot be said that Miss Sykes views the prospects for women, and especially educated women, through rose-coloured glasses. Canada—at all events, those parts in which she stayed—is a land of ceaseless toil. The men work as long as there is any light to see by, only pausing three or four times a day to devour enormous meals; the women slave as hard, or even harder, with this difference, that while the men are for the most part out in the glorious air of the prairie, the women are cooped up in stuffy houses, and still more stuffy kitchens. Of course, in a country where there are a dozen or more men to every woman, almost every girl can get married if she likes; but marriage on the prairie is not quite the catch that it may seem to be to the superfluous woman in England. One of Miss Sykes's employers assured her that, though on the best of terms with her husband, she would never have married him had she known what her life would be. "I haven't a good word to say for the prairie, and I got to hate the very sight of a man, because a man meant preparing a meal. Our ranch was on a main trail, and man after man, as he came along, would drop in and ask for food as a matter of course, and very seldom did he give me a word of thanks for it." In reply to Miss Sykes's question, "But aren't there some women who love the life? In England we hear so much of the 'call of the prairie,'" the mistress replied, "There may be some, but I never met them. All my friends hated the loneliness and the lack of amusement, and the same dull round day after day."

It may be urged against Miss Sykes's criticisms that she found the work so hard because she was totally untrained for it, and, moreover, the better situations were not open to her because she merely applied for temporary posts. Her views, however, are not based upon her personal experience only; she talked with a large number of people in Canada, and she found that, speaking generally, the women on the prairie were worn and old before their time.

In spite, however, of all these drawbacks, Miss Sykes found much to compensate for them. She met with kindness from almost everyone with whom she came in contact, and she came to the conclusion that for the young, efficient and adaptable girl, Canada offers opportunities that are not to be had in the old country. But she must be prepared to work and to work exceedingly hard. "The girl who is a failure in Great Britain will most certainly not be a success in the Dominion."

GENERAL NOTES.

The Turkish Silk Industry.—Brusa and Beirut are the chief centres of the silk industry in Turkey, and the gross annual production of fresh cocoons in the Empire may be estimated at 33,000,000 lbs., valued at about £1,875,000. From 80 to 85 per cent. of this is spun in Turkey, the rest being exported to Continental markets. The spun silks are almost entirely exported, as the native looms are limited to a few hand machines. The average annual silk thread exports amount to about 1,100,000 pounds from Syria, and 1,540,000 pounds from Brusa and Adrianople. Turkey's 1911 silk crop was excellent, but prices were low, partly owing to the new fashions requiring less material, and partly on account of Japanese competition. Bona fide efforts are still being made to open up direct connections with the United States for the sale of Turkish raw silk. Merchants engaged in the silk industry in Turkey have had to face several poor seasons in succession, and there is a tendency to abandon silk for tobacco in some places.

THE U.S.A. HARVEST.—The U.S.A. Government report, issued last week, shows that the harvest this year has surpassed all records. The results compared with last year are as follows:—

	1912.	1911.
Wheat, bushels . .	720,000,000	620,000,000
Corn ,, . .	3,016,000,000	2,531,000,000
Oats ,, . .	1,417,000,000	922,000,000
Rye ,, . .	35,000,000	33,000,000
Barley ,, . .	224,000,000	160,000,000
Potatoes ,, . .	401,000,000	292,000,000
Hay, tons. . . .	72,425,000	55,000,000

Not only are these crops the largest on record, but in most cases, what is highly important, quality is exceptionally good. "It should also be noted," writes Dr. Henry Clews, "that the fruit crops as a whole have been unusually abundant. All food products derived from plant life should be relatively cheap this year, and aid materially in keeping down the cost of living. Only meats are likely to be dear, since the supply of these has been actually declining. If the cost of living is to be reduced, it can only be accomplished by larger product and less waste both of materials and labour. Estimates now place the value of agricultural products this year as high as $10,000,000,000. Possibly this figure is excessive, but it is safe to say our farmers will produce at least $500,000,000 more than last year. With such a marvellous increase in the bounty of Nature, it will be impossible to prevent an active fall and winter trade."

MEETINGS FOR THE ENSUING WEEK.

MONDAY, NOVEMBER 11...Post Office Electrical Engineers, Institution of, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 5 p.m. Mr. C. E. Hay, "Alternate Current Measurement, with special reference to Telephone Cables, Loading Coils, and the Construction of Non-reactive Resistances."

Brewing, Institute of (London Section), Criterion Restaurant, Piccadilly, W., 8 p.m. Messrs. Julian L. Baker, F. E. Day, and H. F. E. Hulton, "A Study of the Organisms Causing Ropiness in Beer and Wort."

Surveyors' Institution, 12, Great George-street, S.W., 8 p.m. Opening Address by the President, the Hon. E. G. Strutt.

British Academy, in the Theatre, Burlington-gardens, W., 5 p.m. (Schweich Lectures.) Rev. C. H. W. Johns, "The Laws of Israel and Babylon." (Lecture II.)

Architectural Association, 18, Tufton-street, S.W., 8 p.m. Mr. J. A. Marshall, "Marbles used in Greek, Roman, and Byzantine Buildings."

Mechanical Engineers, Institution of, Storey's-gate, S.W., 8 p.m. (Graduates' Section.) Mr. G. L. Temple, "Standard and Racing Motor Engines."

TUESDAY, NOVEMBER 12...Sociological, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5.15 p.m. Dr. A. K. Coomaraswamy, "Sati: A Vindication of the Indian Woman."

Asiatic, 22, Albemarle-street, W., 4 p.m. Mr. F. Legge, "Western Manichæism, and the Recent Discoveries at Turfan."

Civil Engineers, Institution of, at the Institution of Mechanical Engineers, Storey's-gate, S.W., 8 p.m. 1. Mr. B. H. Blyth, jun., "The Construction of the New Dock at Methil." 2. Mr. W. Cleaver, "Alterations and Improvements of the Port Talbot Docks and Railway during the Last Decade."

Zoological, Regent's Park, N.W., 8.30 p.m. 1. Mr. H. R. Hogg, "Some Falkland Island Spiders." 2. Mr. B. F. Cummings, "On some Points in the Anatomy of the Mouth-parts of the Mallophaga." 3. Mr. F. F. Laidlaw, "Contributions to a Study of the Dragonfly Fauna of Borneo. Part I.—The Corduliinæ: the Genus *Amphicnemis*." 4. Drs. H. L. Jameson and W. Nicoll, "On some Parasites of the Scoter Duck (*Œdemia nigra*) and their Relation to the Pearl-inducing Trematode in the Edible Mussel (*Mytilus edulis*)." 5. Mr. G. A. Boulenger, "Descriptions of Three New Fishes Discovered in the Gold Coast by Dr. H. G. F. Spurrell."

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 8.30 p.m. Hon. G. E. Foster, "Some Problems of Empire."

Phamaceutical, 17, Bloomsbury-square, W.C., 8 p.m. 1. Mr. T. E Wallis, "Calcium Tartrate and Oxalate from Senna Leaves." 2. Mr. A. N. D. Pullen, "Note on Iodine Ointment."

WEDNESDAY, NOVEMBER 13...Biblical Archæology, Society of, 37, Great Russell-street, W.C., 4.30 p.m. Mr. L. W. King, "Some Unpublished Rock-Inscriptions and Rock-carvings in Turkish Turkestan."

Japan Society, 20, Hanover Square, W., 8.30 p.m. Mr. W. Crewdson, "The Textiles of Old Japan."

Automobile Engineers, Institution of, at the Imperial College of Science, South Kensington, S.W., 8 p.m. Professor W. Watson and Mr. H. Schofield, "Tests of a Daimler Sleeve Valve Engine."

Aeronautical Society, at the United Service Institution, Whitehall, S.W., 8.30 p.m. Mr. A. E. Berriman, "Aeroplanes in the Light of the Military Trials."

Engineers, Junior Institution of, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 7 p.m. Annual Meeting, 8 p.m. Mr. A. H. Tyler, "The Application of CO_2 to Refrigeration."

British Academy, in the Theatre, Burlington-gardens, W., 5 p.m. (Schweich Lectures.) Rev. C. H. W. Johns, "The Laws of Israel and Babylon." (Lecture III.)

THURSDAY, NOVEMBER 14...Concrete Institute, 296, Vauxhall Bridge-road, S.W., 7.30 p.m. Inaugural Address by the President, Mr. E. P. Wells.

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Dr. T. G. Longstaffe, "Views taken in the Himalayas.'

Optical Society, in the Rooms of the Chemical Society, Burlington House, W., 8 p.m. Dr. Max Coque, "The Production of Light by Living Beings."

Electrical Engineers, Institution of, Victoria-embankment, W.C., 8 p.m. Opening Address by the President, Mr. W. Duddell.

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 4.30 p.m. Mr. F. Williams Taylor, "Canadian Loans in London."

FRIDAY, NOVEMBER 15...Geographical Society, Queen's Hall, Langham-place, W., 8.45 p.m. Captain Roald Amundsen, "The Norwegian South Polar Expedition."

Child Study Society, 90, Buckingham Palace-road, S.W., 7.30 p.m. Madame Pujol Ségalas, "Maria Montessori's Method of Self-Education."

SATURDAY, NOVEMBER 16...Child Study Society, 90, Buckingham Palace-road, S.W., 3 p.m. Conference on the Montessori System.

Journal of the Royal Society of Arts.

No. 3,130. VOL. LX.

FRIDAY, NOVEMBER 15, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICE.

ARRANGEMENTS FOR THE SESSION.

The Opening Meeting of the One Hundred and Fifty-Ninth Session will be held on Wednesday evening, November 20th, when an address will be delivered by LORD SANDERSON, G.C.B., K.C.M.G., Vice-President and Chairman of the Council. The chair will be taken at Eight o'clock.

The following arrangements have been made for meetings before Christmas:—

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

NOVEMBER 27. — HAROLD COX, "Political Economy as a Code of Life." SIR GEORGE RANKEN ASKWITH, K.C.B., K.C., will preside.

DECEMBER 4.—A. ZIMMERMANN, "The Manufacture of Sugar from Wood, and its Economic Importance." THOMAS TYRER, F.I.C., F.C.S., will preside.

DECEMBER 11. — DR. F. MOLLWO PERKIN, "Natural and Synthetic Rubber." ROBERT KAYE GRAY, M.I.E.E., will preside.

DECEMBER 18.—JOSEPH PENNELL, "The Pictorial Possibilities of Work."

COLONIAL SECTION.

Tuesday afternoon, at 4.30 o'clock:—

NOVEMBER 26.—PROFESSOR W. H. WARREN, LL.D., M.Inst.C.E., M.Am.Soc.C.E., "The Hardwood Timbers of New South Wales." The RIGHT HON. SIR GEORGE HOUSTOUN REID, G.C.M.G., D.C.L., K.C., High Commissioner for Australia, will preside.

INDIAN SECTION.

Thursday afternoon, at 4.30 o'clock:—

DECEMBER 12. — SIR BRADFORD LESLIE, K.C.I.E., "Delhi, the Metropolis of India."

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., "Methods of Economising Heat." Three Lectures.

December 2, 9, 16.

EXAMINATIONS, 1912.

The Council of the Society have long looked forward to a time when the whole local control of the examinations should be in the hands of the Local Education Authorities. That such a consummation should be attained is but reasonable, seeing that these authorities are the final outcome of the system on behalf of which the Society did its pioneer work now sixty years ago. It was through the Society's organisation that the various mechanics' institutions, which had grown up in the second quarter of the nineteenth century, were systematised and brought into harmonious working. It was the educational centres thus established that provided means for the provision of local science and art schools, and it was the influence and example of these schools that justified the formation of the school boards now developed into the Local Education Authorities, which control elementary and, to a large extent, secondary education throughout the country. Also it was the Society's examinations that inaugurated the whole local examination system, which, whatever its deficiencies and its faults, has beyond question done much valuable work for the promotion of education in England.

For many years past an earnest effort has been made to secure the valuable aid of these important authorities, and much progress has been made. This year a great step in advance was made, when the Council succeeded in securing the aid of the London County Council Education Committee in the superintendence of the examinations.

The Society's examinations for the past fifty years have been conducted through the agency of voluntary committees, and it was felt that these committees could be relied upon for the strict supervision of the examinations. But, to quote a paragraph from the 1911 report of the Council, "the development and competition between the various proprietary institutions

Hosted by Google

which have sprung up of late years, and which it may be added are doing very efficient service in the cause of education, has produced a source of temptation amongst those interested in such institutions, who are anxious to obtain all possible credit for their own schools, and may occasionally be led away to attempt to obtain such credit by illegitimate means." Small as are the temptations to such an illegitimate course, it is yet certain that the stress of competition has occasionally led to fraudulent proceedings. A few such in previous years have been detected and suppressed. Last year it was found necessary to take public action, and this action had the satisfactory result at all events of vindicating the Society's good faith.

But so long as the whole supervision of the examinations was in the hands of unofficial committees, who were of necessity associated with the institutions where the examinations are held, it could not be denied that even though, as was certainly the case, nearly all such committees were far above suspicion, the public could not be expected to place the same implicit reliance in the results of the examinations as if they were conducted under the supervision of some independent authority.

Negotiations were for some time carried on with the London County Council Education Committee, which is the education authority for the County of London, but it was not until after a good deal of inquiry and considerable discussion that the Committee saw their way to accede to the Society's request. Eventually they did so, and with most satisfactory results The final conclusion was not reached until a very short time before the date of the examinations this year, and consequently the arrangements were made under a certain amount of pressure. Nevertheless, they worked with perfect smoothness, and it may be said that they gave general satisfaction to all concerned. This, of course, is not to say that there were not a few complaints of individual hardship; but these were merely infrequent exceptions to the general satisfaction.

The actual changes in the administration were really not considerable, and in no way affected the candidates themselves. The various local committees were asked to send their applications to the L.C.C. Education Office, instead of to the office of the Society. The L.C.C., after inspecting the various centres, arranged which of these should be used for examination purposes and where candidates should sit for examination. All the larger schools were used as centres, and candidates from these schools sat where they were taught. The candidates from the smaller schools were distributed among adjacent centres, and a certain amount of administrative work was thus saved. The most important change really was that the superintendents for the examinations were appointed by the Committee, and were responsible to it, so that the examinations were for the first time in London conducted under the superintendence of independent officers unconnected with the institutions where the examinations were held. The necessary additional cost (£177) was this year borne by the Society's funds; but notice was given that for future years it would have to be provided by a small fee to be paid by the local committees. It was found that the cost of supervision worked out at just 1s. per candidate, and this amount it is now proposed to charge all the London centres, leaving it to the local committees to make their own arrangements for defraying it. It is difficult to see that any objection can be raised to this, because the local committees will in future be relieved from the cost of providing and paying their own superintendents.

If it is found possible in the future to reduce this charge, such reduction will certainly be made, as there is no desire to make any profit out of the charge. There can be no doubt of the value of the assistance rendered by the London County Council, or that its co-operation will add greatly to the value of the examinations, and to the public appreciation of the certificates awarded to the candidates. A similar co-operation has, of recent years, been arranged between the Society and a large proportion of the educational authorities throughout the country, who have established centres of their own, and have in many cases absorbed previously existing local committees. It is the earnest hope of the Council that this system, which has been steadily increasing during the past few years, may still further develop, and that, especially in the great provincial cities, the educational authorities will fall into line with the London County Council, so that, before long, the whole of the Society's examinations may be conducted under official and independent authority.

There is one important result accruing from the official supervision of the examinations, and that is that in London, and wherever the examinations are under such official supervision, the responsibility being taken away from the local committees, their duties are now confined to receiving the entries and collecting the fees from the candidates from their own centres

Hosted by Google

It therefore follows that there is now no necessity for discrimination. Any teaching institution in London can now form its own committee, and can send in its candidates. If such candidates are sufficiently numerous they can be examined at their own centre. It is hoped that this may facilitate the admission of some candidates from institutions where examinations have not been previously held, or where, for whatever reason, they have been discontinued.

In the printed results of the examinations each school gets the credit of the passes of its own candidates, whether or not the school was used as an examination centre.

The examinations this year were held in the County of London and at 401 other centres in the week commencing March 25th, and lasted from the Monday until the following Friday. The results were issued at the following dates:—Advanced Stage, June 15th; Intermediate Stage, July 15th; Elementary Stage, August 15th. Having regard to the very large numbers of papers to be dealt with, no prospect can be held out of the results being issued at earlier dates.

The Commercial subjects included Book-keeping, Accounting and Banking, Shorthand, Typewriting, Economics, Précis-writing, Commercial Law, Commercial History and Geography, Arithmetic, Handwriting, Commercial Correspondence, etc., and Modern Languages. The other subject of examination was Music, divided into Rudiments of Music and Harmony.

The Society this year awarded twenty-six Silver and forty-two Bronze Medals, the former in the Advanced Stage, and the latter in the Intermediate. It also gave away money prizes to the value of £92, besides the prizes, amounting this year to £20—since some were not awarded—provided annually by the liberality of the Clothworkers' Company.

The number of centres at which the examinations are held has increased with the growth of the examinations, and of recent years in rather larger proportion than the number of candidates. As no actual return is made of the number of centres under the London County Council, it is not easy to state the exact number of centres where the examinations were held this year. The total may be taken as slightly over 500, of which 401 were outside London. Of these, 301 were in England and Wales, 46 in Scotland, 53 in Ireland, and one in the Channel Islands (Guernsey).

The total number of candidates at the examinations of 1912 was 28,057 (Advanced, 4,754; Intermediate, 11,855; Elementary, 11,448). This is a decrease of 587 upon the 28,644 candidates of 1911.

This is the first year in which a falling-off in the number of candidates has occurred since 1883, when the present system began. For thirty years the growth has been continuous, sometimes large and sometimes moderate, but there has always been a growth. That it has been interrupted is to be deplored, but the cause is quite certain. It is due to the fact that it was necessary last year to remove from the list of London centres one of the largest, from which of recent years over 2,000 candidates had been entered. But for this most unfortunate necessity, it may fairly be assumed that an increase at least equal to that of last year would have taken place in the number of London candidates. In the numbers examined at centres outside London, there is an actual increase this year, though it is not large enough to counterbalance the falling-off in London.

The decrease was shown in the Advanced and Intermediate Stages, and amounted to 380 in the former and 378 in the latter. In the Elementary Stage there was an increase of 171.

The number of papers worked by the candidates was:—Advanced, 5,483; Intermediate, including Theory of Music, 13,583; Elementary, 14,936, or 34,002 papers in all.

In addition to the 28,057 examined in the annual examination, there were 45 Shorthand candidates at the Special Army Examination, 633 candidates in Colloquial Modern Languages, and 296 in the Practice of Music. The total number of candidates who were examined in all subjects by the Royal Society of Arts during the year ending July last was, therefore, 29,031.

The general results of this year's examinations are given in Table A (page 1139), and a comparative view of the numbers examined during the last six years (1907–12) is given in Table B (page 1140). Table K (page 1143) gives the totals of the Commercial and other examinations for the same period; and Table G (page 1141) the numbers of papers worked.

In the Advanced Stage the falling-off in numbers due to the cause previously mentioned is felt in nearly all the subjects. In one only is there a considerable increase, namely Commercial Law—in this 380 papers were worked as compared with 247 last year, showing an increase of 133. In German there is a small increase of 12—224, as compared with 212. Typewriting and Economics just hold their own, there being an increase of two in the former subject and four in the latter. The largest falling-off is in French,

in which there were 793 papers as compared with 967, or a decrease of 174. Book-keeping shows a falling-off of 109—2,156, as compared with 2,265. In Shorthand there are 93 less than last year. Arithmetic shows a proportionately very heavy loss; last year there were 177, this year there are only 93—not much more than half the number. In English also there is a large proportionate loss—87 against 134, a falling-off of 47. Other subjects showing deficiencies are Commercial History and Geography, 23; Précis-writing, 22; Spanish, 8; Italian, 5; and Portuguese, 2.

With regard to the numbers in the various subjects of the Intermediate Stage, the same remark applies as in the case of the Advanced. Nearly all the subjects show a falling-off, with the important exception of Commercial Correspondence and Business Training, in which there is a large increase of 151, the total being 454 as compared with 303 in 1911, the first year in which this subject was introduced. English, French, and Spanish show small increases; all the others show a falling-off. The largest decrease, as might be expected, is Shorthand, in which there are 224 less. Book-keeping shows a diminution of 160, and Précis-writing a proportionately large falling-off of 124, there being only 144 candidates, whereas last year there were 268. The differences in other subjects are not very large, though the small number of candidates in Italian, 28 last year, is reduced this year to 12.

In Arithmetic, as previously noted, there was a considerable falling-off in the number of papers in the Advanced Stage. This was certainly not made up for by any considerable improvement in the quality of the papers, for the percentage of failures was greater than last year. On the other hand, the percentage of the first-class was slightly larger. It seems hardly worth while to repeat the fact which has so often been stated, that the large percentage of failures in this and in other subjects is due to the entering of candidates who are quite unable to deal with papers of this standard. The examiner remarks that the best papers show, as usual, a high degree of intelligence. In the Intermediate Stage the number of entries fell off slightly; the first-class percentage is nearly the same as in the last two years, the percentage of the second-class is greater, and that of the failures less. The examiner notes a distinct improvement in the style in which the papers were worked. In the Elementary Stage there was a large increase in the number of candidates, but not a proportionate number of passes. The examiner notes that, on the whole, there is an improvement in the style in which the work was done and in general neatness.

In English the percentages show an improvement upon last year, the failures being on the whole proportionately less and the proportion of first-class being greater. The examiner speaks well of the character of the work done both in the Advanced and in the Intermediate Stages.

In Book-keeping the percentage of first-classes in both the upper stages is certainly lower than it ought to be, and the percentage of failures greater. The results of the examination seem to be very similar to those of last year, and certainly do not show any improvement in the standard of the work. In this subject it is specially noticeable that candidates who ought to be content with a Stage II. certificate will unwisely enter themselves for Stage III. In the Elementary Stage it is satisfactory to note that there is evidence of a distinct improvement, as the work appears to be generally better, since with a very large increase—the total being 5,013 as against 4,601—the percentage of failures is a little lower than last year.

Commercial History and Geography in all stages shows an improvement, especially in the two higher stages. Here, again, candidates and teachers should read the examiner's remarks.

In Shorthand the Examiner expresses his regret that there has been very evident deterioration in the work of the candidates entering for Stage III., and attributes this result to the lack of sufficient general education in the candidates. There is a distinct falling-off in the number of first-class certificates, a falling-off which is certainly not attributable to any increased difficulty in the paper or to severity on the part of the examiner, for a careful examination of his results made it quite clear that it was impossible, without a lowering of the character of the examination, to give better marks to a larger proportion of the papers which were sent in. In the Intermediate Stage the results were rather better. The proportion of first-class papers was rather higher, and the proportion of failures rather lower than last year. In the Elementary Stage there was a decided improvement, for though the number of entries was larger, the percentage of passes shows an increase of nearly four.

In Typewriting there was a larger proportion of first-class papers in Stage III., but unfortunately there was also a larger proportion of

Hosted by Google

failures. In Stage II., on the other hand, there was a falling-off in the first-class, a slight increase in the second, and a very distinct increase in the proportionate number of failures. The causes of these results are carefully discussed by the examiner in his report, to which teachers and candidates are referred. In the Elementary Stage, although there was a slight decrease in the number of papers, the percentage of passes shows an increase of 2 per cent.

In Economics both stages show an improvement. The proportion of successes has been greater, and the character of the work on the whole indicates advance.

As to the subject of Commercial Law, the examiner remarks that there was a striking increase from 247 to 380, or nearly 54 per cent., in the number of papers worked, and this was not accompanied by any decrease in the quality of the work. He adds that, speaking generally, the results of the examination are quite encouraging, as not only has the number of papers increased very considerably, but the number of failures has decreased, and the number of first-class certificates has nearly reached the normal standard of the years before 1911.

The results of the examination in Précis-writing are somewhat disappointing in both stages, and compare rather unfavourably with last year, although the papers set are believed to have been slightly easier.

As regards Accounting and Banking, the examiner says: "The number of candidates at the examination held this year was 476, as against 499 last year and 407 in 1910; showing a decrease of 23 as compared with last year. The percentages of candidates who passed are a little lower, and the percentage of failures a little higher, than last year. From the institution of this examination the results have been particularly satisfactory, the highest percentage of failures being only 32·12 (1907), while the average of the past seven years is 29·297; and it must be remembered that the standard is a high one. This points to the large majority of candidates having become well acquainted with the subject before presenting themselves for examination."

The results of the examination in Commercial Correspondence and Business Training, a subject in which an examination was held for the first time in 1911, are on the whole very satisfactory, both as regards the number of candidates and the character of the papers. The first-class papers were more numerous, though there was a slight increase in the percentage of failures. But this is not to be wondered at, considering the increase in the number of entries. At present this examination has only been held in the Intermediate Stage, but the results seem to justify the addition of an examination in the Advanced Stage after another year.

With regard to the corresponding subject in the Elementary Stage—Handwriting and Correspondence—the results this year show a distinct improvement upon last. With a slightly diminished number of entries, there was a definite increase in the passes. The examiner's report, on the whole, is favourable.

The examiner in French considers the character of the papers worked in all three stages satisfactory, and as not showing any very great difference from those of recent years. In the Advanced Stage the failures were about the same, and the number of first-class larger. In the Intermediate Stage the failures were rather larger, and the successes, both first and second-class, slightly smaller.

In German the examiner says that the papers in Stage III. were, as a whole, well done, and the results were most satisfactory. The essays were good, and the translations into German better than in previous years. Curiously enough, exactly the contrary result was noted as regards Stage II. In the Elementary Stage there was some improvement in the translations into German, but the standard is still, in the examiner's opinion, very low.

In Italian the numbers entering this year were smaller than usual, but the papers on the whole seem to have been better. The proportion of failures is less both in Stage III. and in Stage II., and the proportion of first-classes higher. The examiner speaks well of the translations into Italian.

In Spanish the results in the two higher stages were, on the whole, satisfactory. But in the Elementary Stage, although the paper was not a difficult one, it was not well done.

In Portuguese the results were, on the whole, a little better than last year.

There were a few candidates in Russian, Danish, Norwegian, Swedish, and Japanese; but none this year in Hindustani. It is proposed next year to add an examination in Arabic, as information has been received that a few candidates are ready to enter for it.

The examinations in Rudiments of Music and Harmony were carried on as usual at the same time as the Commercial examinations, and the results appeared as part of the results of the

Hosted by Google

Intermediate Stage. The total number of candidates shows a trifling decrease on that of last year. This year there were 688, compared with 691 in 1911, 619 in 1910, 699 in 1909, 716 in 1908, 641 in 1907, and 637 in 1906. In Rudiments of Music, 391 candidates presented themselves, whereas last year there were 398. In Harmony there were 297, as compared with 293. Of the 391 candidates in Rudiments of Music, 306 passed and 85 failed. Of the candidates in Harmony, 203 passed and 94 failed. The examiner, on the whole, reports favourably on the results, which do not differ very much from those of recent years.

A report on the Practical Examinations in Music has been published in the *Journal*.* 296 candidates were examined—an increase of 13 as compared with the 283 last year; of these 220 passed and 76 failed. These examinations have been carried on continuously since they were established in 1879. The numbers for a long time did not vary very widely. In the first year 117 candidates were examined. The numbers increased gradually to 276 in 1891, and to 393 in 1895. The largest number yet examined was 566 in 1900. During the last few years there has been a small but steady diminution in the numbers. The standard has not varied much, but is now a little higher than it was. The general level of attainment is considered by the examiners to be about the same as for the last few years.

For the Viva Voce Examinations held this year in Modern Languages 633 candidates entered—an increase on last year, when there were 583. These examinations were started in 1902, when 280 candidates were examined. The numbers rose to 681 in 1905, after that there was a slight falling-off. Examinations were held this year in French, German, Spanish, and Italian; there have also in previous years been a few entries for Portuguese, but none entered during the last few years. The numbers were: French, 476; German, 123; Spanish, 22; Italian, 12. Table L (page 1143) gives in detail the results of this year's examinations.

The examiner in colloquial French reports that the examination was in no way below the level of its predecessors; there was an increase of 50 in the number of candidates examined, and the percentage of successes was higher. The German examiner says that the number of candidates examined was rather larger than in 1911, and the percentage of successes higher; he considers that the general results were extremely satisfactory. The results in Spanish are still rather unsatisfactory, though a little better than last year; the numbers entering were not so large, but the proportion of failures was smaller. Though the numbers entering in Italian is never very large, the candidates appear to be fairly well taught, and the proportion of failures is always very small.

At the request of the Army Council, the Council, in 1907, arranged to hold a special annual examination in Shorthand for soldiers, and such an examination has been held every year since. In 1907 there were 40 candidates; in 1908, 84; in 1909, 60; in 1910, 66; in 1911, 64. This year there were 45 entries. There were 25 centres in the United Kingdom, India, South Africa, and Malta. These examinations were held on February 15th. Of the 45 candidates, 31 passed and 14 failed. In the Advanced Stage there were 3 first-class and 5 second-class. In the Intermediate Stage there were 7 first and 16 second. The percentage of successes is about 69, which is not quite as good as last year, which was 73. Still this is much above the average of Shorthand examinations.

The Examination Programme for 1913 was issued two months ago. In it will be found the fullest possible information about the examinations, a syllabus of each stage of each subject, and the papers set in 1912.* The attention of both teachers and students may be drawn not only to the syllabuses but also to the remarks of the various examiners on the results of last year. It will be found that these contain many valuable and helpful suggestions, and the work of the candidates year after year shows that far too little attention is paid to them. Teachers especially are earnestly recommended to study these remarks, as they ought to be guided by them in the instruction they give to their pupils. The remarks of each examiner follow his examination paper in the Programme for each year, and have also been printed at the end of the published lists of results, in the hope—probably vain—that they may be read.

The regulations for the Examinations in Music (Theory and Practice), and those for the Viva Voce Examinations in Modern Languages, are also given at full length.

* See *Journal*, July 12th, 1912, Vol. LX. p. 815.

* The price of the Programme (133 pages) is 3*d*., post free 4½*d*. Copies can be obtained on application to the Secretary of the Royal Society of Arts, Adelphi, London, W.C. Programmes containing the papers set in 1905, 6, 7, 8, 9, 10, and 11 can also be obtained at the same price. The regulations and syllabuses can also be had separately (without the papers) price 1*d*., by post 1½*d*.

THE MOZAMBIQUE RUBBER INDUSTRY.

There is said to be no industry in Portuguese East Africa with a brighter prospect than that of rubber exploitation. The rubber forests are extensive, and the landolphia vines from which the rubber is extracted are profuse. With organisation and working capital there is no reason why the export of rubber should not shortly increase to 500 tons annually, while the percentage of rubber to waste in the vines is small as compared, for instance, with the output of latex from a young Ceara tree, the abundance of the vine and its remarkable powers of recuperation are factors which more than make up for the low percentage. There are at present in use two native methods of extracting rubber. The first, that of incision or tapping, is followed by all natives south of the Zambesi Valley, and it produces a high-class rubber known as "Mozambique pink," second only, according to the United States Consul at Lourenço Marques, to the best Para on the European market. The other method of extraction, known as pounding, is generally followed in the Mozambique and other northern districts. There the bark is stripped from the roots of the vines, or from the vines, and is cooked over a slow fire and pounded until the bark is finally pounded out, leaving a mass of rubber in all stages of crudity. This rubber is known as Mozambique rooty. It is classed very low, but a large concern now working in the Mozambique district has perfected the system of pounding to the point of producing a rubber which is rapidly approaching the classification of Mozambique pink. A strange truth has come to light in regard to the landolphia, and that is that while vines are frequently killed by incision or tapping, this seldom happens with the vine which is cut down almost to the ground after maturity. It is also a notable fact that large parts of the root of a vine can be dug up and cut off without killing the vine. In the Mozambique district there are places where natives have been cutting roots from the same vines year after year. The recognition of this fact will make an enormous difference in the estimates of the capacity of the forests. Most of the rubber areas in the province are well known, and up to a year ago they were all in the hands of the Government. The promulgation of the law of September 2nd, 1909, gave an impetus to private enterprise, and since the law came into force large districts have been taken up, and final title has been ceded by the Government on approximately 450,000 acres of forest. These large tracts are being worked mostly on a small scale, owing to lack of capital, and some are not being worked at all.

In the terms of the land law referred to above, it is most difficult, if not impossible, for a foreign capitalist to acquire directly a tract large enough to give returns on a big investment, say 50,000 hectares (123,000 acres). Such a grant would be subjected to the approval of the provincial council, the Governor-General, and the home government, and would finally come up for auction. However, various local groups of Portuguese, with the ten years' residence in Portuguese colonies prescribed by the said law as a condition to privilege, have established their claims, and combined their lots of 10,000 hectares (24,600 acres) to each individual, in large tracts of from 40,000 hectares (98,400 acres) to 100,000 hectares (246,000 acres) in extent. The rubber industry in Portuguese East Africa is not for the moneyless settler, however industrious. It offers big returns to the capitalist, by reason of the fact that he can work on a large scale. A concessionaire of say 50,000 hectares (123,000 acres) must split up his lands into five or six districts. Each district has a collecting station and a store, for the native has little idea of cash. When he has worked he must be paid in goods.

With the installation of machinery the semi-skilled labour of the native becomes less and less necessary. In a well-equipped concern his share in the production of rubber will be summed up in the simple work of gathering the bark of roots and vine. This can be done equally well by African or coolie. During 1910, rubber to the value of £75,000 was exported from the province of Mozambique, and this dropped to £42,500 in 1911. The great decrease in this important item can be traced to two causes—the break of the rubber boom and consequent collapse in prices, and the disturbed conditions which forced a duly organised rubber concern in the province to suspend operations during six months. The break in prices is by far the more important factor.

THE MOTHER-OF-PEARL INDUSTRY IN BETHLEHEM.

The chief industry to-day in Bethlehem is the manufacture of articles of religious devotion and ornaments from mother-of-pearl. The methods and tools used are mostly quite primitive in character, as are also the buildings in which the workmen carry on their trade. The principal products are carved shells, on which religious scenes are depicted, beads, and rosaries. The material known as "pearl waste," from which beads and rosaries are made, is very largely imported from the United States, and the American market is also the largest purchaser of these goods. In the manufacture of beads, which is now the most important branch of the industry, a workman's outfit is primitive, consisting of files, borers, and a simple wooden device for holding the irregularly shaped pieces of pearl waste. The American Consul at Jerusalem says that this last is made of a short, round piece of wood, sawn in half lengthwise, fastened together at one end, and encircled by a loose iron ring. The piece of pearl shell is placed between the loose wooden ends, and the ring is hammered toward it until the grip is tight. The workman then files the part of shell which extends to the desired diameter, it is reversed in the holder, and finally a rounded piece of perhaps one to three inches in length is secured. When

Hosted by Google

a number of these pieces have been prepared they are cut to bead size, a hole is bored in each bead, and it is rounded to the desired shape. Then to give the beads a smooth surface, they are placed in special crockery vessels with a little water, and are kept in motion in these vessels, rubbing against the sides and each other until they are smooth, but not polished. To give them a gloss and sheen, they are finally placed in boiling water, to which a weak solution of nitric or muriatic acid is added, and when removed from this they are passed through a succession of cooling waters. There are three usual shapes—those flat on two sides, round, and oval. The beads are strung on cords, silk or wire, and always on the latter in the case of rosaries. For these last also crosses and hearts are made of mother-of-pearl, with a small metal figure attached to the cross. Silver crosses and hearts are used to a slight extent. The wages of the bead workmen are not high. Those who make the beads earn from 1*s*. 4*d*. to 2*s*. 8*d*. per day. The women and girls who string them receive from 6*d*. to 1*s*. per day. The files used are mostly of German and Belgian manufacture, with some of English make. With the exception of those employed for the finest work, which are imported new, old files are brought in and recut in Bethlehem. Formerly this was done by hand, but a machine has recently been secured from Europe for resharpening the old files. It is claimed that these resharpened files yield better results than new ones, and they are much less expensive. The borers are made locally from steel rods, especially imported for the purpose. The white-metal wire, for the rosaries and the silver accessories, is chiefly of French manufacture.

THE SPANISH MELON INDUSTRY.

The fame of the fine winter melons grown in the Valencia district, of which 12,000 to 15,000 are exported annually, has extended over the greater part of Europe. Classified in the order of harvesting season of each variety, the following are the principal species of melon cultivated: "Pudents" are the earliest in season, but have little else to recommend them, as they are considered insipid, and, as their name indicates (*pudrir*, to rot), decay quickly in handling and transportation. "Chincholats," or "Escrits," so called from the fanciful resemblance of the lines on the surface of the skin to Arabic writing, are small in size and of spherical shape. They are shipped in small quantities to the United Kingdom, where they bring fair prices because of their early appearance on the market (from the end of May to the end of June), but their flavour is said to be inferior, and the trade in them is precarious, as, if picked when too nearly ripe, they are very likely to decay in transportation. "Canarios," so named from their bright canary colour, are a hardy variety, which form the basis of Valencia melon exports to northern Europe in July and August. They are oval in shape, with tough rind and firm pulp, the layer of which, however, is not thick, as the seed cavity is disproportionately large. They withstand the sea voyage remarkably well, but are not distinguished by fine flavour. "Negros" and "bronceados" (black and bronze coloured), the genuine winter melons of the Valencia district, are by far the best varieties, and receive the greatest care in selection and cultivation. The former are of a dark, unchanging green colour, of an elongated oval or cylindrical shape, and unusually large, weighing from nine to sixteen pounds. The "bronceados" are oval, or slightly conical in shape, with thick pulp and small seed cavity. Both these varieties at their best are very fine, and probably nothing superior of their kind can be produced in any part of the world. The Valencia system of melon-growing requires seed beds and transplanting, according to the American Consul there. The seeds are planted in the beds in clusters of five or six on a layer of animal manure wrought into a thick paste by the addition of water, each cluster being deposited in slight depressions in the surface about eight or nine inches apart. The bed is then covered with a light sprinkling of dry pulverised manure, which is kept moist by occasional spraying with water. Transplanting takes place when the two lateral branches of the plant are thrown out and the tip of the central growth is just appearing. The more delicate plants are discarded, and only the healthiest and most vigorous utilised. In the Alicante district, a little south of Valencia, seed is planted definitely in the open, in pits about a yard apart, in which organic manure has been mixed with the soil. Water melons are harvested in the early autumn, and are suspended in loops of esparto cordage from nails in the beams of roofs and lofts, where they keep, with but little deterioration, for six months or more. The water-melon of the Valencia district and, indeed, of all Spain, appears to be a fixed species that has undergone little modification for centuries. The varying degrees of colour and different percentages of sugar that distinguish the pulp of fruit grown in different localities in Spain, appear to depend almost entirely on soil conditions rather than varieties, and the Valencia water-melon differs little from similar fruit grown in northern Africa. It does not attain very great size, but has a remarkably thin rind and highly-coloured meat, and is of superior quality. The principal pests from which water-melons of all kinds suffer in Spain are mildew, scale and snails. The scale, which is said to belong to the family of the rose scale, is the most difficult to combat successfully, especially when dull, foggy, warm weather conditions favour its rapid propagation. The dry, parching winds that blow at irregular intervals during the summer from the semi-arid interior of the country effectively arrest the progress of this scale, and, if continued two or three days, will exterminate it altogether. Snails are dealt with in a practical and economical way by turning flocks of ducklings into the melon plantations.

ENGINEERING NOTES.

Communication between India and Ceylon.—"Quos Deus vult perdere prius dementat." This well-known maxim of dubious latinity, and unknown classical parentage, of which, by the way, there is a parallel in the common phrase "mess of pottage," which is not to be found in any part of the Bible, is brought to mind by circumstances which have led to the recent launch of the first of three geared-turbine steamers which are to convey passengers and goods across the narrow strait between India and Ceylon. The steam service will connect the railways of each country, pending the construction of a bridge or causeway, which is almost a certainty of the future. The main-line railways of the two countries are of the same gauge, 5 feet 6 inches. But, with full knowledge of the future possibility of a bridge, or at least the establishment of what is known as a train ferry—viz., a service of steamers, which would carry trains bodily across, such as are in use in many parts of the world—the Indian authorities adopted a 3 feet 3⅜ inches gauge for the railway leading to the ferry. This renders nugatory either of the above possibilities. Colombo, in Ceylon, is one of the finest ports of the world, large expenditure having been made upon it, while the coasts of Southern India are remarkably deficient in good harbours, so that, if the gauge had not been broken, an uninterrupted channel for the export of all Southern India produce would have been provided at the Ceylon port. As matters stand, three unnecessary transhipments will be the result, from the wide gauge to the narrow gauge, to the steamer on the Indian side, and from the steamer to the train on the Ceylon side, the cost of which will probably be equal to something like a hundred miles of extra rail carriage, and may amount to vastly more than the extra interest on the capital which might have been required for the wider line, especially in a flat country like Southern India. This is written under the heading of an engineering note, but the ineptitude which has led to the diversity of gauges in railways, destined ultimately to be connected, in India, Africa, and Australia, has been largely due to politicians, who have disregarded the counsels of their engineering advisers.

The Ghent Exhibition.—Machinery is to be the special feature of the Ghent Exhibition to be held next year. The buildings will cover fifty acres more ground than those at Brussels. France has taken fifty per cent. more space than at the latter Exhibition. For the first time abroad, the British machinery exhibits will be collective in character, following foreign precedent, and the Machine, Tool and Engineering Association, as at Olympia, will be the means of carrying out this principle. The machinery hall will measure 19,000 square metres, and the railway gallery will have nearly 6,000 square metres. These areas are considerably larger than were devoted to engineering exhibits at Brussels.

Corrugated Ships.—The application of corrugation to the sides of ships was described at the Royal United Service Institution, on October 16th. This is not a mere proposal, for the principle has been tried in actual practice, four vessels so built having been launched, while two more are on the stocks. Captain MacIlwaine, R.N., who introduced the subject, claimed that a vessel of this kind was stronger than the plain ship, that she was steadier at sea, and that her stability was greater, that vibration was much reduced, and that she was faster for the same horse-power, or more economical in fuel for the same speed; also, that she would stand collisions of all sorts better. The corrugated ship differs from the plain one, in that she has two corrugations, or projections, running in a fore and aft direction, below the load line. From the top of the upper corrugation to the bottom of the lower is 13 feet 3 inches, and the groove between might be said to be of similar dimensions to the corrugations. From the inner edges of the frames the corrugations project 22 inches, they taper fore and aft until they merge into the normal form of the ship's ends. But Captain MacIlwaine explained that it was not to be understood that any sort of corrugations would suit any ship, or that no more than two would be carried; experiments were necessary until the most suitable form was discovered. Judging from this description of the lecturer, it would at first appear that much additional skin friction would be introduced, but this would seem to be more than compensated for by the lead which the corrugations give to the propeller, increasing its effectiveness, for it is stated that, taking the figures for different voyages, an average slip of 2 per cent. in fairly fine weather could be justifiably claimed. In plain ships of the same class and build as the corrugated ship, it was assumed that a fair average slip would be about 13 per cent.; this meant a saving of a very considerable amount of fuel. The principle does not appear to have been tried with twin-screw ships.

Electric Steel Works.—The Stobie Steel Company, of Sheffield, are erecting new works on Tyneside for the installation of electric steel melting furnaces, this site having been selected as current can be obtained on the north-east coast under more favourable conditions than in Sheffield. The works will at first consist of a 15-ton three-phase steel melting furnace, a 5-ton two-phase furnace for special steels, and a 3-cwt. alloy-melting furnace. A very fine installation of this description has been recently erected at Ugine, in Savoy; there they have the advantage of abundance of water-power. The current is received at 20,000 volts, and is transformed down to 65 volts. There is a full description of the latter works in "La Technique Moderne," of Paris, Vol. IV., 1912.

The Water-cooled Blast Furnace.—Thin-lined furnaces, cooled by a film of water, in place of the ordinary solid brick lining, were tried some

Hosted by Google

years ago at the Gelsenkerchen works in Germany. Since then, they have been adopted in several places in the United States, notably by the Carnegie Steel Company and the Illinois Steel Company, and more recently in the works of the Tennessee Coal, Iron, and Steel Rail Company, and of the Detroit Iron and Steel Company. They are claimed to show a distinct superiority over the thick-lined furnace in operation, and their establishment in so many centres seems to justify the statement.

Dynamometer Car for Japan.—A dynamometer car is being constructed in the United States for the Japanese Government. It is 48 feet long by 8 feet 6 inches in width, and is of the hydraulic dynamometer type. It is capable of measuring traction up to 80,000 lbs., also recording speed, time, distance, vibration, and buffer thrust. Its maximum speed is eighty-five miles per hour. There is an axle generator and storage battery to supply current for operating the recording apparatus, and for lighting. There are vacuum brakes, and the journals, wheels, and equipment generally correspond to that of the Japanese rolling-stock. It is significant that the car, though built for 3 feet 6 inches gauge, is specified to be so constructed that it can be altered to suit the 4 feet 8½ inches gauge if necessary.

The Leicester, Derby, and Nottingham Water Supply.—The first instalment of these works, which will utilise the waters of the Howden and Derwent Rivers, was recently opened. The Howden dam, which has now been put into service, is 1,080 feet long by 117 feet high, and is 176 feet wide at the base, built of solid masonry. At one place it was necessary to excavate to the great depth of 172 feet to reach a water-tight bed. When the whole scheme is complete, there will be a supply of 33,000,000 gallons of pure water daily. The cost is estimated at £6,645,000.

Panama Canal Electric Power.—Those who are familiar with the plan of the canal will remember that the level of the artificial lake, which will be held up by the Gatun dam, will be 85 feet above sea-level, and locks at each end of the raised water will enable the ships using the canal to ascend from, and descend to, the ocean level. This lift in the traffic was rendered necessary to diminish the amount of cutting in the hills forming the backbone of the isthmus. Advantage is to be taken of the head of water at the locks at the Atlantic end to erect an electrical power-station, in order to supply the power requirements of the canal itself and electrical energy generally for the canal zone. The turbo-generators will be of the vertical type, and the rotating element will be suspended from an over-hung thrust-bearing, supported by the top shield of the generator. The turbine will be set in a heavy masonry foundation, and the generator will be super-imposed upon the turbine casting. Each turbine is rated at 2,250 kilowatts, at a speed of 250 revolutions per minute, and will consume, approximately, 500 cubic feet of water per second at full load. The generator is to be rated at 2,000 kilowatts, and will deliver three-phase 25-cycle current at a potential of 2,200 volts. A high voltage transmission line will connect the station with the existing steam generating stations at Miraflores, which will be held in reserve.

GENERAL NOTES.

International Building Trade Exhibition, Leipzig, 1913.—An International Building Trade Exhibition (with special exhibitions) will be held at Leipzig from May to October, 1913. The Exhibition has for its object to give a comprehensive survey of the progress made in matters concerning public buildings and dwellings in all civilised countries. As the building trade will be represented in all its branches, great value is attached to the greatest possible clearness of arrangement and systematic division of the material. To ensure this a special department for science and art in a separate building will be constructed, which will allow of arranging the exhibits according to the material instead of the exhibitor. In this building the most prominent masterpieces of architecture will be illustrated by models, drawings, photographs and memoirs, arranged systematically in groups, which will bear suitable references to the stands in the remaining exhibition buildings where are exhibited the respective products of the industry.

Fire-proof Roofing.—A cheap and durable fire-proof roofing is made in France with asbestos and Portland cement, in the proportion of one-fifth of asbestos fibre, one-fifth asbestos powder, and three-fifths Portland cement. The mortar, which must be carefully mixed, is pressed into wooden moulds about two feet square and one-fifth of an inch thick with the trowel. These slabs, when perfectly set, are used in the same way as slates and nailed to the woodwork of the roof. This kind of roofing, which is very light and durable, is suitable for sheds and out-buildings.

Production of Petroleum in Rumania.—The production of petroleum in Rumania during the first six months of the present year amounted to 861,901 tons, as compared with 690,353 tons for the corresponding period of 1911, showing an increase of 171,548 tons, or nearly 25 per cent. for this year. The output would have been considerably greater but for serious fires which occurred in the oil-fields of Moreni-Stravopoleos and Moreni-Bana, when considerable losses were incurred from this cause. Fires are of frequent occurrence at borings where the oil rises to the surface, in spite of the care displayed by the companies in order to prevent them. Great improvements have been made of late years in the working of the oil-fields in Rumania.

Hosted by Google

CATTLE-BREEDING IN BRAZIL.—The Brazilian Government, being particularly anxious to encourage cattle-breeding in Brazil, has taken measures to establish stud and model breeding farms in the pastoral districts. The object of these farms is the theoretical and practical study of all questions relating to cattle-breeding and the improvement of the various stocks. The stud farm at Pinheiro in the State of Rio de Janeiro has already been installed, while those at Ribeirao Preto in the State of Sao Paulo, and at Lages in the State of Santa Catharina, are in course of construction. Two establishments that will give special attention to the improvement of the native species of cattle, and to the breeding of a type of horse which will serve for remounts for the army, have already been opened, one in the State of Parana, and the other in the State of Rio de Janeiro, while a third is shortly to be opened at Urberaba in the State of Minas Geraes.

EXHIBITION OF AUTO-CARS AND MOTOR MACHINERY AT BRUSSELS, 1913.—An important exhibition of auto-cars and motor machinery is announced to be held at Brussels next year under the auspices of "La chambre Syndicale de l'automobile et du Cycle de la Belgique." A considerable space will be reserved for agricultural machinery as applied to "moto-culture," both at home and in the colonies. The exhibition will take place from January 11th to January 22nd, 1913.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, NOVEMBER 18...British Architects, Institute of, 9, Conduit-street, W., 8 p.m. Mr. J. L. Ball, "Bath and Wells."

Sanitary Engineers, Institute of, Caxton Hall, Westminster, S.W., 8 p.m. Mr. E. van Putten, "Intercepting Traps in House Drains."

TUESDAY, NOVEMBER 19...Statistical Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. Dr. Dudfield, "Still-Births in Relation to Infantile Mortality."

Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. 1. Mr. L. Gaster (Hon. Secretary) will present a report of progress during the vacation with special reference to his visits to the Continent and to the United States. 2. Mr. J. W. Johnston, "Ancient Forms of Lamps." 3. Mr. H. T. Harrison, "A New Illumination Photometer." 4. Mr. W. C. Clinton, "Some Simple Colour Boxes." 5. Messrs. J. S. Dow and V. K. Mackinney, "Photography in Illuminating Engineering." 6. "Miner's Lamps."

Civil Engineers, at the Institution of Mechanical Engineers, Storey's-gate, S.W., 8 p.m. Discussion on papers by Mr. B. H. Blyth, jun., "The Construction of the New Dock at Methil," and Mr. W. Cleaver, "Alterations and Improvements of the Port Talbot Docks and Railway during the Last Decade."

WEDNESDAY, NOVEMBER 20...ROYAL SOCIETY OF ARTS. John-street, Adelphi, W.C., 8 p.m. Inaugural Address of the 159th Session, by Lord Sanderson, Vice-President and Chairman of the Council.

Meteorological Society, at the Surveyors' Institution, Great George-street, S.W. 7.30 p.m. 1. Dr. H. R. Mill, "The Unprecedented East Anglian Rainfall of August 26th, 1912." 2. Mr. A. P. Jenkin, "A Three-year Period in Rainfall."

Geological Society, Burlington House, W., 8 p.m.

Microscopical Society, 20, Hanover-square, W., 8 p.m. 1. Rev. Hilderic Friend, "British Euchytraeids. IV.—The Genus Henlea." 2. Messrs. E. Heron-Allen and Arthur Earland, "Saccammina Psammosphœra (North Sea No. 2)."

United Service Institution, Whitehall, S.W., 3 p.m. Professor C. W. C. Oman, "Courts-Martial of the Peninsular Army, 1809–1814."

THURSDAY, NOVEMBER 21...Mining and Metallurgy, at the Geological Society, Burlington House, W., 8 p.m.

Ophthalmic Opticians, Institute of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m.

Royal Society, Burlington House, W., 4.30 p.m.

Antiquaries, Society of, Burlington House, W., 8.30 p.m.

Linnean Society, Burlington House, W., 8 p.m. 1. Dr. A. B. Rendle, "Mr. P. A. Talbot's collection of plants from Southern Nigeria, illustrated with lantern-slides." 2. Mrs. Longstaff, "Impressions of the feeding tracks of *Limax maximus* and *Helix aspersa.*" 3. The Rev. G. Henslow, "Vegetable Mechanics." 4. Miss Nellie Bancroft, "Some Indian Jurassic Gymnosperms."

Chemical Society, Burlington House, W., 8.30 p.m. 1. Messrs. H. B. Baker and M. Baker, "The Change in the Boiling Points of the Trioxide and Tetroxide of Nitrogen on Drying." 2. Mr. E. Feilmann, "The Tendency of Atomic Weights to approximate to Integral and Semi-integral Values." 3. Messrs. F. B. Power and H. Browning, jun., "The Constituents of Taraxacum Root." 4. Messrs. S. A. Brazier and H. McCombie, "The Condensation of α-keto-β-anilino-$\alpha\beta$-diphenylethane and its Homologues with Phenyl Carbimide and Phenyl Thiocarbimide." 5. Messrs. G. Senter and F. Bulle, "Neutral Salt Action. Part II.—The Influence of Sodium Salts of Organic Acids on the Rate of Hydrolysis by Alkali." 6. Mr. O. L. Brady, "The Constitution of Aconitine." (Preliminary Note.)

Historical, 7, South-square, Gray's Inn, W.C., 5 p.m. Mr. E. Beck, "The Crutched Friars."

Numismatic Society, 22, Albemarle-street, W., 6.30 p.m.

FRIDAY, NOVEMBER 22...Fine Art Guild, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 7.15 p.m. Mr. Carl Henschel, "The Sun as an Engraver."

Physical Society, at the Imperial College of Science, South Kensington, S.W., 5 p.m.

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. 1. Mr. J. W. Anderson, "Vapour-Compression Refrigerating Machines." 2. Dr. J. H. Grindley, "A Contribution to the Theory of Refrigerating Machines."

Correction.—With reference to the statement in an article on "Soya Bean Production in Manchuria," which appeared in the *Journal* of August 16th last (page 902), that "the United States have shown their appreciation of the bean by abolishing the import duty," Messrs. Bigland, Sons, and Jeffreys write to say that they have made inquiries at Washington, and are advised that the duty on soya beans into America still remains at 45 cents per bushel, and is not likely to be removed. The statement in the *Journal* was made on the authority of a resumé of a report of the Chamber of Commerce of Trieste. The Editor regrets that it is incorrect, and desires to thank Messrs. Bigland, Sons, and Jeffreys for drawing his attention to the matter.

CONTENTS.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country. It is one of the three oldest of the learned and scientific Societies in the kingdom, for at the date of its foundation only the Royal Society and the Society of Antiquaries were in existence.

At present the Society numbers nearly four thousand members. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Members are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday evening during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Members also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Sir Henry Trueman Wood, at the Society's House, John Street, Adelphi, London, W.C.

ENGLISH.

Mason's Senior English Grammar. Revised and Augmented by A. J. ASHTON, M.A., Examiner in English to the College of Preceptors. Crown 8vo. 3*s.* 6*d.*

Matriculation Précis. By S. E. WINBOLT, M.A., Christ's Hospital. 1*s.* 6*d.*; or with Key, 1*s.* 6*d.*

Aids to the Writing of English Composition. By FRED W. BEWSHER, St. Paul's School. 1*s.* net.

Essays and Essay Writing for Public Examinations. By A. W. READY, B.A., Army and University Tutor, formerly Scholar of Wadham College, Oxford. Sixth Edition. Crown 8vo. 3*s.* 6*d.*

London Chamber of Commerce Journal.—"We feel convinced that Mr. Ready's method is one by which composition can be successfully taught in schools, and quite dispels the statement made by many teachers that composition cannot be taught."

Précis and Précis Writing. By A. W. READY, B.A. Fourth Edition, revised. Crown 8vo., with full Key, 3*s.* 6*d.*

An Outline History of English Literature. By W. H. HUDSON, Staff Lecturer in English Literature to the Extension Board, London University. 2*s.* 6*d.* net.

Introduction to English Literature. By HENRY S. PANCOAST. Third Edition, enlarged and reset. 656 pages. Crown 8vo. 5*s.* net.

A First View of English Literature. By HENRY S. PANCOAST and PERCY VAN DYKE SHELLY. Crown 8vo. With 44 Illustrations and 2 Maps. 5*s.* net.

ARITHMETIC, &c.

Public School Arithmetic. By W. M. BAKER, M.A. Headmaster of the Military and Civil Department at Cheltenham College, and A. A. BOURNE, M.A., late Head Mathematical Master at Cheltenham College. COMPLETE EDITION, 3*s.* 6*d.*; or with Answers, 4*s.* 6*d.*

The Student's Arithmetic. By W. M. BAKER, M.A., and A. A. BOURNE, M.A. Second Edition with or without Answers, 2*s.* 6*d.*

This work contains all the Exercises of the Public School Arithmetic, with a minimum of book-work.

WORKS BY CHARLES PENDLEBURY.

A New School Arithmetic. Eighth Edition. 4*s.* 6*d.* Or, in Two Parts, 2*s.* 6*d.* each. EXAMPLES. Separately, 3*s.*; or, Part I., 1*s.* 6*d.*; Part II., 2*s.*

A Preparatory Arithmetic. With or Without Answers. 1*s.* 6*d.*

A Junior Arithmetic. 1*s.* 6*d.*; or with Answers, 2*s.* (The Answers separately, 6*d.* net.) EXAMPLES. Separately, 1*s.*; or, with Answers, 1*s.* 6*d.*

New Shilling Arithmetic. 1*s.*; or, with Answers, 1*s.* 4*d.*
*** Similar to the "Junior Arithmetic," except that all treatment of the first four rules is omitted.

Commercial Arithmetic. By CHARLES PENDLEBURY, M.A., & W. S. BEARD. Seventh Edition. Crown 8vo., 2*s.* 6*d.* Part I., separately, Second Edition, 1*s.*; Part II., 1*s.* 6*d.*

~~This Arithmetic is based upon the scheme suggested by the~~ Education Departments for Students in Evening Continuation Classes. Throughout the book examples have been taken from Papers set at the Royal Society of Arts and other similar examinations.

MODERN LANGUAGES.

The Direct Method of Teaching French. By D. MACKAY, M.A., of Ayr Academy, N.B., and F. J. CURTIS, Ph.D., Professor at the Akademie, Frankfurt-am-Main.
FIRST FRENCH BOOK. Illustrated. 1*s.* net.
SECOND FRENCH BOOK. Illustrated. 1*s.* 6*d.* net.
TEACHERS HANDBOOK. 1*s.* net.
SUBJECT WALL PICTURE (Coloured). 7*s.* 6*d.* net.

Educational News—"Provides the most complete set of apparatus for the practice of 'The New Method' that we have yet seen."

Bell's French Picture Cards. Edited by H. N. ADAIR, M.A., Senior French Master at the Strand School. Two sets are now ready, each containing 16 different Cards, printed in Colours, with Questionnaire on back of each. Price 1*s.* 3*d.* net per set. Packets containing 16 of any one Card may also be had at the same price.

Bell's French Course. By R. P. ATHERTON, M.A., Assistant Master at Haileybury. Complete in Two Parts. Illustrated. 1*s.* 6*d* each.

Bell's First French Reader. By R. P. ATHERTON, M.A. 1*s.*

Gasc's Concise Dictionary of the French and English Languages. Sixth Edition, revised. Medium 16mo. Treble Columns, xii+941 pp., 3*s.* 6*d.* Also in Two Parts, 2*s.* each.

Bell's First German Course By L. B. T. CHAFFEY, M.A., Assistant Master at Eton. Illustrated. 2*s.*

Bell's First German Reader. By L. B. T. CHAFFEY, M.A., Illustrated. 2*s.*

A Practical German Grammar. By CALVIN THOMAS. Fourth Edition, revised. Crown 8vo., 5*s.*

A German Reader and Theme-Book. By CALVIN THOMAS, Professor in Columbia University, and W. A. HERVEY. Crown 8vo. 438 pp., 4*s.* 6*d.*

A Spanish Primer. By the Rev. A. C. CLAPIN. 1*s.*

ECONOMICS AND FINANCE.

Economics. A Briefer Course. By HENRY ROGERS SEAGER, Professor of Political Economy in Columbia University. 8vo. 6*s.* 6*d.* net.

This new book is intended for the use of students who cannot afford time for the same author's well-known "Introduction to Economics."

An Introduction to Economics. By HENRY ROGERS SEAGER, Professor of Political Economy in Columbia University. New and Revised Edition. 8vo. 10*s.* 6*d.* net.

The History, Principles and Practice of Banking. By J. W. GILBART, F.R.S., formerly Director and General Manager of the London and Westminster Bank. New Edition, revised and brought up to date by ERNEST SYKES, B.A. Oxon., Secretary of the Institute of Bankers. 2 vols, Sm. Post 8vo. 5*s.* each.

Financial News.—"'Gilbart on Banking' has long attained to a classical position, and ought to be an indispensable part of the education of every banker."

250 MEDALS & PRIZES!!

The CHEAPEST Textbook in the English Language is

THE STUDENT'S COMPLETE

COMMERCIAL BOOK-KEEPING

ACCOUNTING & BANKING,

By ARTHUR FIELDHOUSE, Accountant, Technical College, Huddersfield.

(Send postcard to P.O. Box D.50, Huddersfield, for copy Index; or Postal Order for 4/-, when book will be despatched by return of post.)

FIFTEENTH EDITION. 800 PAGES. 320 EXERCISES WITH ANSWERS.

Post Free, 4/-. 500 Commercial Terms. 1911 Exam. Papers.

TWO HUNDRED AND FIFTY GOLD, SILVER & BRONZE MEDALS have been secured by Candidates using this work, in addition to the FIRST PRIZES of the ROYAL SOCIETY OF ARTS for Book-keeping as well as for ACCOUNTING and BANKING, the LONDON CHAMBER OF COMMERCE, and NATIONAL UNION OF TEACHERS, and the INCORPORATED ACCOUNTANTS.

It is the only Reliable and Complete Guide to all Examinations.

PITMAN'S JOURNAL, in "Answers to Correspondents," says:—"If H.S. has worked through all the examples in Fieldhouse's Book, he should certainly have as good a knowledge of Book-keeping as is ordinarily necessary."

THE DESK BOOK IN ACCOUNTANTS' OFFICES.

This **up-to-date** Book includes Banking, Cheques and Bills of Exchange; **Limited Partnership Act, 1907**; Income Tax and **Finance Act, 1911**; **Companies' Consolidation Act, 1908**; Bankruptcy Statements; Branch and Cost A/cs., Double A/c. System, Insurance A/cs., and **Published A/cs.** Every page stamped with **Twentieth Century Methods.**

During my studies for the Intermediate and Final Examinations of the **Incorporated Accountants** I worked the majority of the Exercises in your text-book. It is a very useful and **marvellous book.** Its value is wonderful, and I am sure it **cannot be beaten** for the money. I recommend it to everybody who asks my opinion on the subject. G. E. SAUNDERS, **First Place** and **Gold Medallist.**
